Creating and Managing Customer Sites
with CCA

Contents

Introduction	3
Customer Site	3

Introduction

Make sure your PC meets recommended minimum requirements. If this is your first time connecting CCA, be sure your PC meets the prerequisites: <https://supportforums.cisco.com/docs/DOC-9779>

Download the latest CCA (3.0 used in this lab) from <http://www.cisco.com/go/configassist>. While Office Manager (OM) may be used as an end user admin tool for CCA configured systems, it must not be running when CCA is running (they are mutually exclusive in run mode).

Connect your PCs Ethernet NIC to a LAN switch port on the UC 500, disable your wireless NIC and any VPN clients and you are ready to begin.

CCA is the element manager for many products in the Smart Business Communications System suite (SBCS). It can manage each deployment in a one at a time fashion. CCA offers the ability to save customer 'sites' in a way that allows for saving and reuse later, which will save you time on initial connection discovery as well as make available the capability to manage other elements connected to the site.

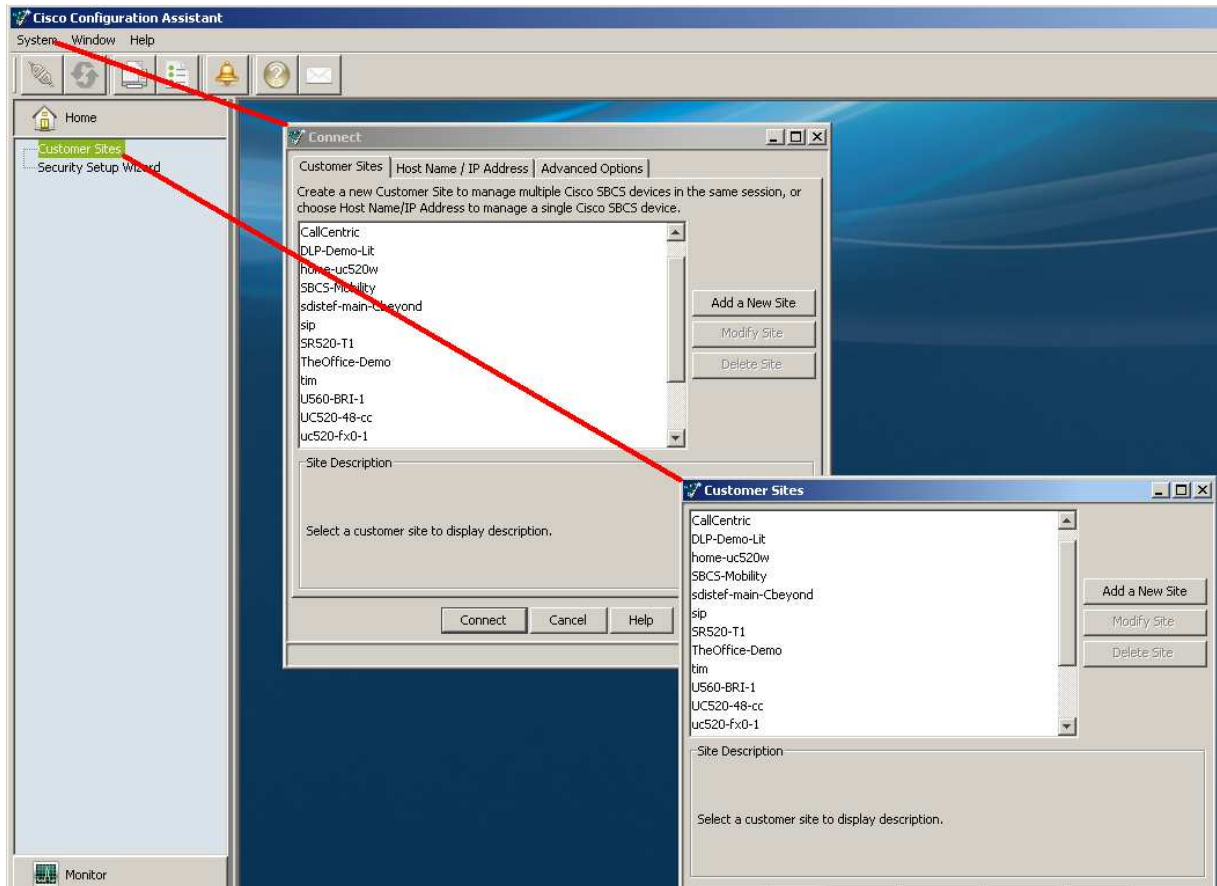

CCA uses both Cisco Discovery Protocol (CDP) and Apple Bonjour discovery protocol to fill its topology view. This view can be annotated as you wish and saved. Topology is about the only thing CCA saves on the PC for reuse and discovers everything else from the underlying managed elements each time it is connected. This assures CCA is operating on the most current & exact running configuration of your system. Note: There is no prevention built into CCA to detect if more than one connection to the managed elements exists, so you must due diligence to insure this does not happen as a general practice.

Initial discovery allows use of a specific IP (like the UC 500 at 192.168.10.1) or a seed unit or network. In this lab, we will discover the UC500 and then 'add to site' adjacent elements of the SBCS to the site. While the option exists to "connect to IP address" to manage only UC 500, this isn't a recommended practice and does not support features than span SBCS (like Video Monitoring or switch port management , access points, etc.).

It's a good practice to statically assign IP addresses to elements which are relied upon regularly in subsequent CCA sessions. If power was cycled of a device connection was interrupted, it could potentially receive a different DHCP IP address, and will need to be added to the site each time this happens and you reconnect CCA.

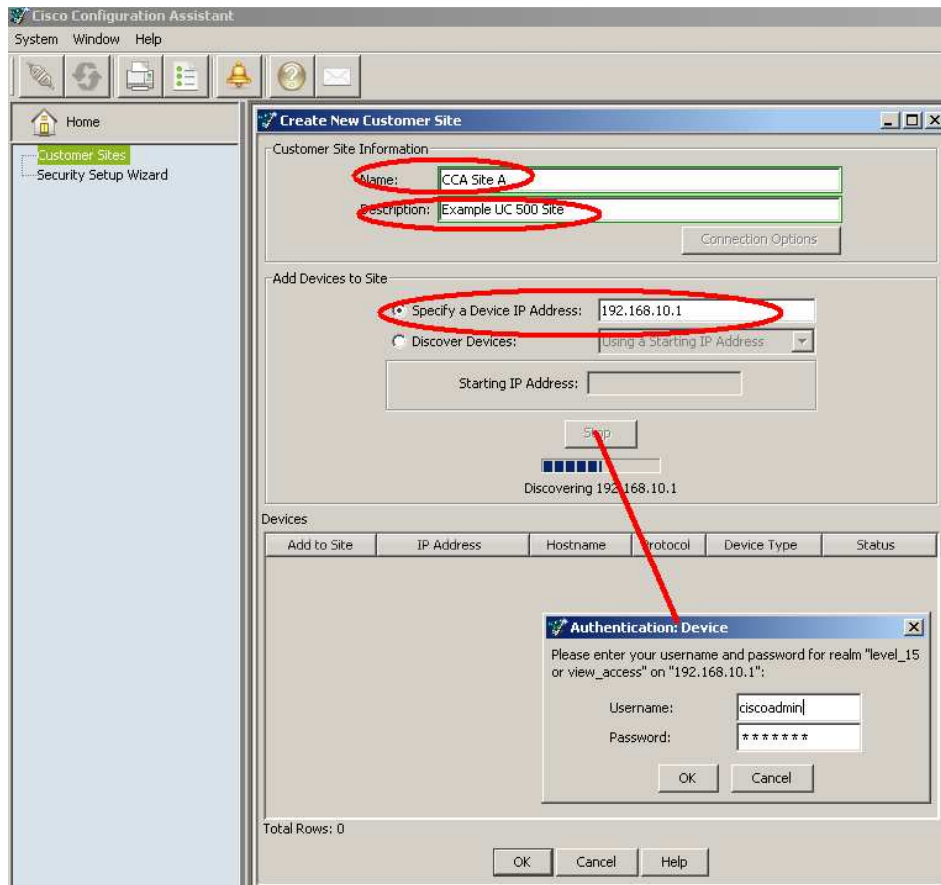

Customer Site

You can see there are two ways to connect to a site/ manage a site. Using the menu bar System: Connect or using the HOME> Customer Site GUI:

In this lab, we will add a new site using the UC 500 default IP address of the data VLAN (yours may vary).

When you click start after entering a description and discovery method, you will be prompted for credentials, which are that of the UC 500.

After authentication, the UC500 is discovered:

Create New Customer Site

Customer Site Information

Name:

Description:

Add Devices to Site

☒ Specify a Device IP Address:

☐ Discover Devices:

Starting IP Address:

Devices

Add to Site	IP Address	Hostname	Protocol	Device Type	Status
<input checked="" type="checkbox"/>	192.168.10.1	UC_540	https	UC540W-FXO-K9	<input checked="" type="checkbox"/> Discovered

Total Rows: 1

Now click OK and then Connect:

Connect

Customer Sites | Host Name / IP Address | Advanced Options

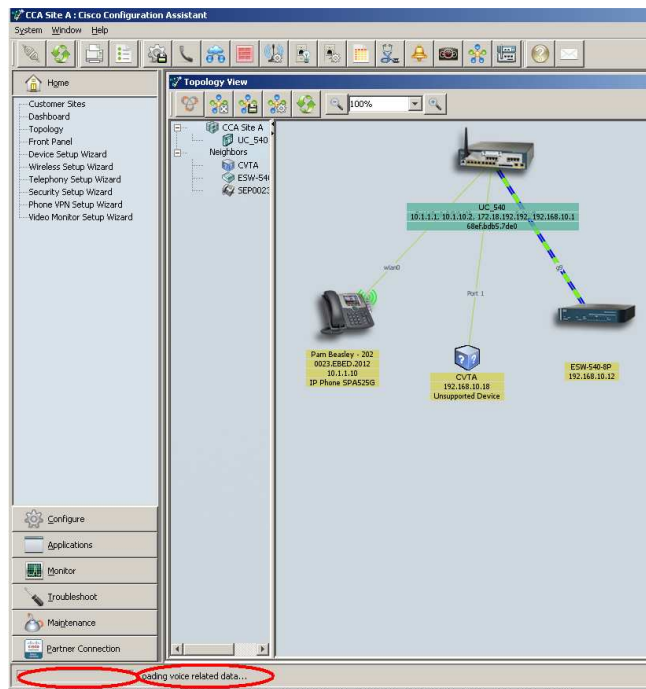

Create a new Customer Site to manage multiple Cisco SBCS devices in the same session, or choose Host Name/IP Address to manage a single Cisco SBCS device.

CCA Site A

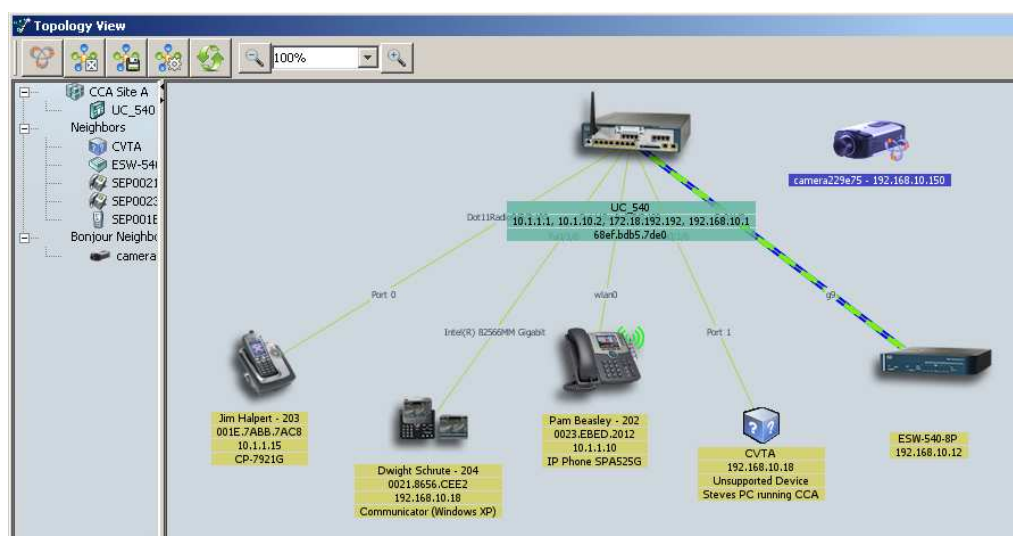

Site Description

Example UC 500 Site

Let CCA complete its discovery of IOS/CME and CUE. Do not perform any actions until this is completed.

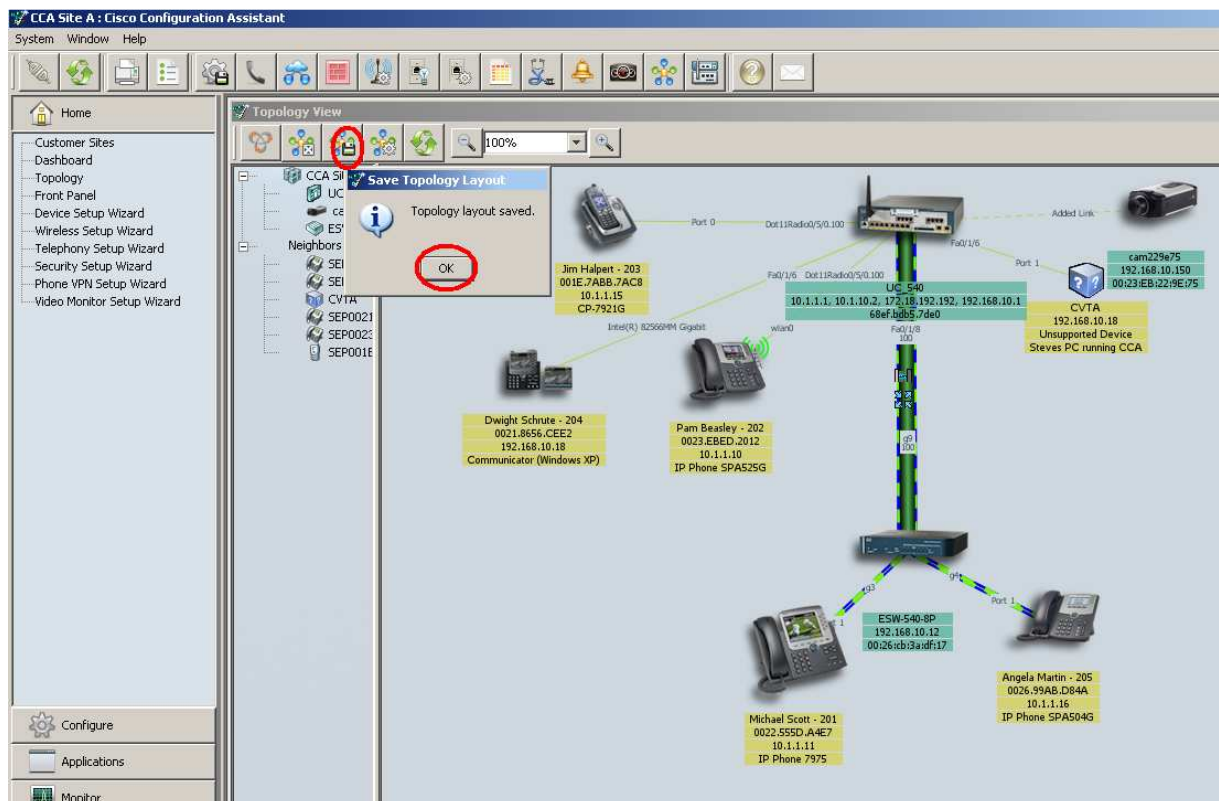

In the above topology, notice the PC I am using to connect to CCA also runs Cisco Video Telephony Application (also known as CUA or Cisco Unified Video Advantage) allowing me to have point to point video calling when my PC is tethered behind a traditional Cisco IP Phone or running Cisco IP Communicator (CIPC) soft phone. I did a right mouse click and annotated as shown. I also run CIPC on my PC and have one wireless SPA525G and C7921 mobile Wifi phone. Finally, bonjour found the PVC2300 camera. Wireless connections to the integrated AP of the UC 540 appear as an adjacent device as well as the ESW Switch.

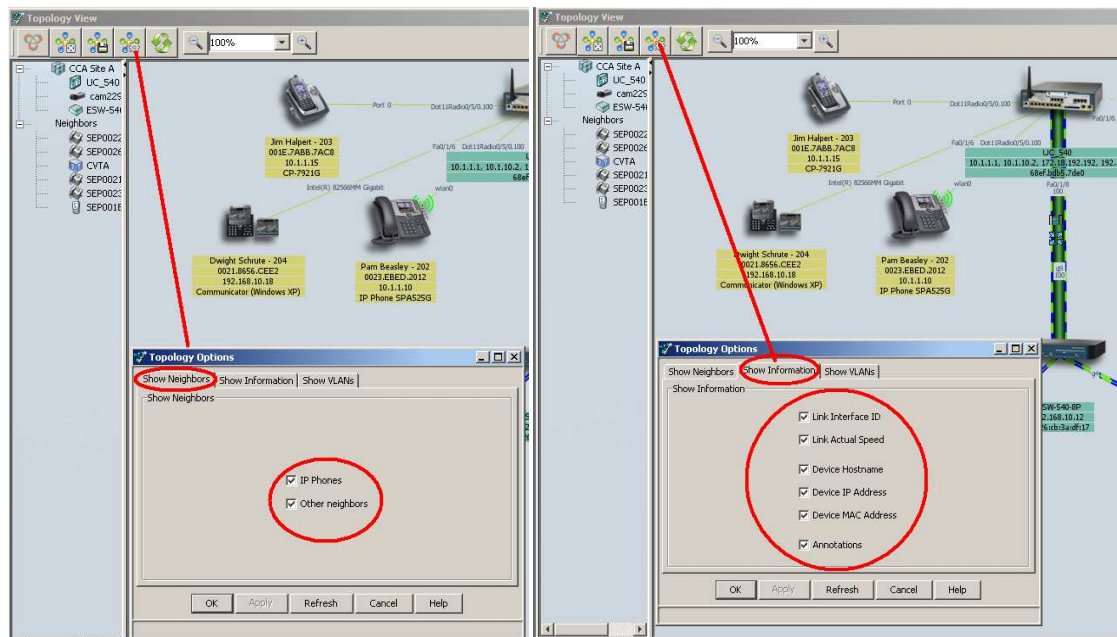

Now we right mouse click on the switch and the camera and select ADD TO SITE. Do them one at a time. Enter credentials for each (you will be challenged if the credentials are different from existing elements in a site; so the shortcut is to make them the same).

I also clicked on the UC540 ICON and then CTRL-Clicked the Camera so I could then right mouse click and add a line between the two. Notice the phones connected to the switch now appear as its adjacent neighbors. Then rearranged the ICONS as I like and clicked SAVE TOPOLOGY:

If your CCA display doesn't display details as verbose as this, click Topology Options and navigate to the tabs and enable what you want to see as follows.

Remember Saving Topology DOES NOT SAVE configuration. You must remember to click the CCA SAVE ICON in the menu bar to save all elements in the site.

Also, become familiar with the rediscover ICON so you don't have to wait for automatic rediscovery.

Just to give a few fast examples, you can now see the elements of the site integrated where appropriate into the CCA drawers and menus:
