## CHAPTER 1

## **Overview** 1-1

SSL Cryptography Overview 1-1

    SSL Public Key Infrastructure 1-2

        Confidentiality 1-3

        Authentication 1-3

        Message Integrity 1-5

    SSL Handshake 1-5

ACE SSL Capabilities 1-7

ACE SSL Functions 1-9

    SSL Termination 1-10

    SSL Initiation 1-11

    End-to-End SSL 1-11

ACE SSL Configuration Prerequisites 1-12

CHAPTER 2

**Managing Certificates and Keys** 2-1

- SSL Digital Certificates and Key Pairs 2-2
- Generating Key Pairs and Certificate Signing Requests 2-5
  - Generating an RSA Key Pair 2-5
  - Creating and Defining a CSR Parameter Set 2-6
    - Creating a CSR Parameter Set 2-7
    - Specifying a Common Name 2-8
    - Specifying a Country 2-9
    - Specifying a State or Province 2-9
    - Specifying a Serial Number 2-10
    - Specifying a Locality 2-10
    - Specifying an Organization Name 2-11
    - Specifying an Organizational Unit 2-11
    - Specifying an E-mail Address 2-12
  - Generating a Certificate Signing Request 2-12
- Preparing a Global Site Certificate 2-14
- Importing or Exporting Certificate and Key Pair Files 2-14
  - Importing Certificate and Key Pair Files 2-15
  - Exporting Certificate and Key Pair Files 2-17
- Upgrading an SSL Certificate 2-18
- Verifying a Certificate Against a Key Pair 2-19
- Deleting Certificate and Key Pair Files 2-20
- Creating a Chain Group 2-21
- Configuring a Group of Certificates for Authentication 2-23

CHAPTER 3

**Configuring SSL Termination** 3-1

- SSL Termination Overview 3-2
- ACE SSL Termination Configuration Prerequisites 3-4

SSL Termination Configuration Quick Start	3-4
Creating and Defining an SSL Parameter Map	3-7
Adding a Cipher Suite	3-10
Ignoring Expired or Invalid Server Certificates	3-13
Defining the Close-Protocol Behavior	3-14
Defining the SSL and TLS Versions	3-14
Configuring the SSL Queue Delay	3-15
Configuring the SSL Session Cache Timeout	3-16
Rejecting Expired Client Certificates	3-17
Creating and Defining an SSL Proxy Service	3-17
Associating an SSL Parameter Map with the SSL Proxy Server Service	3-18
Specifying the Key Pair	3-19
Specifying the Certificate	3-19
Specifying the Certificate Chain Group	3-20
Enabling Client Authentication	3-21
Using CRLs for Client Authentication	3-22
Configuring Downloaded CRLs for Client Authentication	3-23
Configuring a DNS Client	3-24
Enabling Domain Lookups	3-25
Configuring a Default Domain Name	3-26
Configuring a Domain Name Search List	3-26
Configuring a Domain Name Server	3-27
Configuring SSL URL Rewrite	3-28
Configuring an Action List	3-28
Defining the SSL URL Rewrite String and Port	3-29
Associating an Action List with a Layer 7 HTTP Load-balancing Policy Map	3-31
Creating a Layer 3 and Layer 4 Class Map for SSL Termination	3-32
Creating a Layer 3 and Layer 4 Policy Map for SSL Termination	3-33
Creating a Layer 3 and Layer 4 Policy Map	3-33

Associating the Layer 3 and Layer 4 Class Map with the Policy Map 3-34

Associating an SSL Proxy Server Service with the Policy Map 3-35

Applying the Policy Map to the VLANs 3-36

    Applying the Policy Map Globally 3-36

    Applying the Policy Map to a Specific VLAN 3-36

Example of an SSL Termination Configuration 3-37

**INDEX**

## Preface

---

This guide describes how to configure the Secure Sockets Layer (SSL) features on a Cisco 4700 Series Application Control Engine (ACE) appliance. It describes how to configure certificates and keys, SSL termination, SSL initiation, and end-to-end SSL.

You can configure the ACE by using the following interfaces:

- The command-line interface (CLI), a line-oriented user interface that provides commands for configuring, managing, and monitoring the ACE.
- Device Manager graphic user interface (GUI), a Web browser-based GUI interface that provides a graphical user interface for configuring, managing, and monitoring the ACE.

This preface contains the following major sections:

- [Audience](#)
- [How to Use This Guide](#)
- [Related Documentation](#)
- [Symbols and Conventions](#)
- [Obtaining Documentation, Obtaining Support, and Security Guidelines](#)
- [Open Source License Acknowledgements](#)

# Audience

This guide is intended for the following trained and qualified service personnel who are responsible for configuring the ACE:

- System administrator
- System operator

# How to Use This Guide

This guide is organized into the following chapters:

Chapter	Description
<a href="#">Chapter 1, Overview</a>	Provides an overview of Secure Sockets Layer (SSL) cryptography and the ACE SSL features.
<a href="#">Chapter 2, Managing Certificates and Keys</a>	Describes how to manage SSL certificate and key pair files on the ACE, including how to import and export certificate and key pair files.
<a href="#">Chapter 3, Configuring SSL Termination</a>	Describes how to configure the ACE as an SSL proxy server to perform SSL termination between itself and a client.
<a href="#">Chapter 4, Configuring SSL Initiation</a>	Describes how to configure the ACE as an SSL proxy client to perform SSL initiation between itself and a web server.
<a href="#">Chapter 5, Configuring End-to-End SSL</a>	Describes how to configure the ACE as an SSL proxy client and an SSL proxy server to perform both SSL termination and SSL initiation, providing an end-to-end SSL solution between the client and the web server.
<a href="#">Chapter 6, Displaying SSL Certificate and Key Pair Information</a>	Describes how to display data and statistics related to your ACE SSL configuration.

## Related Documentation

In addition to this guide, the ACE documentation set includes the following documents:

Document Title	Description
<i>Release Note for the Cisco 4700 Series Application Control Engine Appliance</i>	Provides information about operating considerations, caveats, and command-line interface (CLI) commands for the ACE.
<i>Cisco Application Control Engine Appliance Hardware Installation Guide</i>	Provides information for installing the ACE appliance.
<i>Regulatory Compliance and Safety Information for the Cisco Application Control Engine Appliance</i>	Regulatory compliance and safety information for the ACE appliance.
<i>Cisco 4700 Series Application Control Engine Appliance Quick Start Guide</i>	Describes how to use the ACE appliance Device Manager and CLI to perform the initial setup and VIP load-balancing configuration tasks.
<i>Cisco 4700 Series Application Control Engine Appliance Administration Guide</i>	Describes how to perform the following administration tasks on the ACE: <ul style="list-style-type: none"> <li>• Setting up the ACE</li> <li>• Establishing remote access</li> <li>• Managing software licenses</li> <li>• Configuring class maps and policy maps</li> <li>• Managing the ACE software</li> <li>• Configuring SNMP</li> <li>• Configuring redundancy</li> <li>• Configuring the XML interface</li> <li>• Upgrading the ACE software</li> </ul>

Document Title	Description
<i>Cisco 4700 Series Application Control Engine Appliance Virtualization Configuration Guide</i>	Describes how to operate your ACE in a single context or in multiple contexts.
<i>Cisco 4700 Series Application Control Engine Appliance Routing and Bridging Configuration Guide</i>	Describes how to perform the following routing and bridging tasks on the ACE: <ul style="list-style-type: none"> <li>• Configuring Ethernet ports</li> <li>• Configuring VLAN interfaces</li> <li>• Configuring routing</li> <li>• Configuring bridging</li> <li>• Configuring Dynamic Host Configuration Protocol (DHCP)</li> </ul>
<i>Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide</i>	Describes how to configure the following server load-balancing features on the ACE: <ul style="list-style-type: none"> <li>• Real servers and server farms</li> <li>• Class maps and policy maps to load balance traffic to real servers in server farms</li> <li>• Server health monitoring (probes)</li> <li>• Stickiness</li> <li>• Firewall load balancing</li> <li>• TCL scripts</li> </ul>
<i>Cisco 4700 Series Application Control Engine Appliance Application Acceleration and Optimization Configuration Guide</i>	Describes how to configure the application acceleration and optimization features of the ACE. This guide also provides an overview and description of those features.

Document Title	Description
<i>Cisco 4700 Series Application Control Engine Appliance Security Configuration Guide</i>	<p>Describes how to configure the following ACE security features:</p> <ul style="list-style-type: none"> <li>• Security access control lists (ACLs)</li> <li>• User authentication and accounting using a Terminal Access Controller Access Control System Plus (TACACS+), Remote Authentication Dial-In User Service (RADIUS), or Lightweight Directory Access Protocol (LDAP) server</li> <li>• Application protocol and HTTP deep packet inspection</li> <li>• TCP/IP normalization and termination parameters</li> <li>• Network Address Translation (NAT)</li> </ul>
<i>Cisco 4700 Series Application Control Engine Appliance System Message Guide</i>	Describes how to configure system message logging on the ACE. This guide also lists and describes the system log (syslog) messages generated by the ACE.
<i>Cisco 4700 Series Application Control Engine Appliance Command Reference</i>	Provides an alphabetical list and descriptions of all CLI commands by mode, including syntax, options, and related commands.
<i>Cisco 4700 Series Application Control Engine Appliance Device Manager GUI Configuration Guide</i>	Describes how to use the Device Manager GUI, which resides in flash memory on the ACE, to provide a browser-based interface for configuring and managing the appliance.
<i>Cisco CSS-to-ACE Conversion Tool User Guide</i>	Describes how to use the CSS-to-ACE conversion tool to migrate Cisco Content Services Switches (CSS) running-configuration or startup-configuration files to the ACE.

# Symbols and Conventions

This publication uses the following conventions:

Convention	Description
<b>boldface font</b>	Commands, command options, and keywords are in <b>boldface</b> . Bold text also indicates a command in a paragraph.
<i>italic font</i>	Arguments for which you supply values are in <i>italics</i> . Italic text also indicates the first occurrence of a new term, book title, emphasized text.
{ }	Encloses required arguments and keywords.
[ ]	Encloses optional arguments and keywords.
{x   y   z}	Required alternative keywords are grouped in braces and separated by vertical bars.
[x   y   z]	Optional alternative keywords are grouped in brackets and separated by vertical bars.
string	A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks.
screen font	Terminal sessions and information the system displays are in <i>screen font</i> .
<b>boldface screen font</b>	Information you must enter in a command line is in <b>boldface screen font</b> .
<i>italic screen font</i>	Arguments for which you supply values are in <i>italic screen font</i> .
^	The symbol ^ represents the key labeled Control—for example, the key combination ^D in a screen display means hold down the Control key while you press the D key.
< >	Nonprinting characters, such as passwords are in angle brackets.

Notes use the following conventions:

**Note**

---

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the publication.

---

Cautions use the following conventions:

**Caution**

---

Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

---

For additional information about syntax formatting and navigating the ACE CLI, see the *Cisco 4700 Series Application Control Engine Appliance Command Reference*.

## Obtaining Documentation, Obtaining Support, and Security Guidelines

For information on obtaining documentation, obtaining support, providing documentation feedback, security guidelines, and also recommended aliases and general Cisco documents, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

## Open Source License Acknowledgements

The following acknowledgements pertain to this software license.

### OpenSSL/Open SSL Project

This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>).

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com).

This product includes software written by Tim Hudson (tjh@cryptsoft.com).

## License Issues

The OpenSSL toolkit stays under a dual license, i.e. both the conditions of the OpenSSL License and the original SSLeay license apply to the toolkit. See below for the actual license texts. Actually both licenses are BSD-style Open Source licenses. In case of any license issues related to OpenSSL please contact [openssl-core@openssl.org](mailto:openssl-core@openssl.org).

### OpenSSL License:

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

**Original SSLeay License:**

© 1995-1998 Eric Young (eay@cryptsoft.com). All rights reserved.

This package is an SSL implementation written by Eric Young (eay@cryptsoft.com).

The implementation was written so as to conform with Netscapes SSL.

This library is free for commercial and non-commercial use as long as the following conditions are adhered to. The following conditions apply to all code found in this distribution, be it the RC4, RSA, lhash, DES, etc., code; not just the SSL code. The SSL documentation included with this distribution is covered by the same copyright terms except that the holder is Tim Hudson (tjh@cryptsoft.com).

Copyright remains Eric Young’s, and as such any Copyright notices in the code are not to be removed. If this package is used in a product, Eric Young should be given attribution as the author of the parts of the library used. This can be in the form of a textual message at program startup or in documentation (online or textual) provided with the package.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. All advertising materials mentioning features or use of this software must display the following acknowledgement:

“This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)”.

The word ‘cryptographic’ can be left out if the routines from the library being used are not cryptography-related.

4. If you include any Windows specific code (or a derivative thereof) from the apps directory (application code) you must include an acknowledgement: “This product includes software written by Tim Hudson (tjh@cryptsoft.com)”.

**THIS SOFTWARE IS PROVIDED BY ERIC YOUNG “AS IS” AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.**

The license and distribution terms for any publicly available version or derivative of this code cannot be changed. i.e. this code cannot simply be copied and put under another distribution license [including the GNU Public License].

## Overview

---

Secure Sockets Layer (SSL) is an application-layer protocol that provides encryption technology for the Internet. SSL ensures the secure transmission of data between a client and a server through a combination of privacy, authentication, and data integrity. SSL relies upon certificates and private-public key exchange pairs for this level of security.

This chapter contains the following major sections:

- [SSL Cryptography Overview](#)
- [ACE SSL Capabilities](#)
- [ACE SSL Functions](#)
- [ACE SSL Configuration Prerequisites](#)

## SSL Cryptography Overview

The Cisco 4700 Series Application Control Engine (ACE) appliance uses a special set of SSL commands to perform the SSL cryptographic functions between a client and a server. The SSL functions include server authentication, private-key and public-key generation, certificate management, and data packet encryption and decryption.

The ACE supports SSL Version 3.0 and Transport Layer Security (TLS) Version 1.0. The ACE understands and accepts an SSL Version 2.0 ClientHello message, known as a hybrid 2/3 hello message, allowing dual-version clients to communicate with the ACE. When the client indicates SSL Version 3.0 in the Version 2.0 ClientHello, the ACE understands that the client can support SSL Version 3.0 and returns a Version 3.0 ServerHello message.

**Note**

---

The ACE cannot pass network traffic if the client supports only SSL Version 2.0.

---

A typical SSL session with the ACE requires encryption ciphers to establish and maintain the secure connection. Cipher suites provide the cryptographic algorithms required by the ACE to perform key exchange, authentication, and Message Authentication Code (MAC). See the “[Adding a Cipher Suite](#)” section in [Chapter 3, Configuring SSL Termination](#), for details about the supported cipher suites.

This section provides an overview of SSL cryptography as implemented in the ACE and contains the following topics:

- [SSL Public Key Infrastructure](#)
- [SSL Handshake](#)

## SSL Public Key Infrastructure

SSL provides authentication, encryption, and data integrity in a Public Key Infrastructure (PKI). PKI is a set of policies and procedures that establishes a secure information exchange between devices. Three fundamental elements characterize the PKIs used in asymmetric cryptography:

- [Confidentiality](#)
- [Authentication](#)
- [Message Integrity](#)

These three elements provide a secure system for deploying e-commerce and a reliable environment for building virtually any type of electronic transactions, from corporate intranets to Internet-based e-business applications.

## Confidentiality

*Confidentiality* ensures that unintended users cannot view the data. In PKIs, confidentiality is achieved by encrypting the data through a variety of methods. In SSL, specifically, large amounts of data are encrypted using one or more symmetric keys that are known only by the two endpoints. Because the symmetric key is usually generated by one endpoint, it must be transmitted securely to the other endpoint. The ACE supports the use of the *key exchange* mechanism for the secure transmission of a symmetric key between the ACE and its peer.

In key exchange, one device generates the symmetric key and then encrypts it using an asymmetric encryption scheme before transmitting the key to its peer. Asymmetric encryption requires that each device has a unique key pair that consists of a public key and a private key. The two keys are mathematically related; data that is encrypted using the public key can only be decrypted using the corresponding private key, and vice versa. A device shares its public key with its peer but must keep its private key a secret.

The security of asymmetric encryption depends entirely on the fact that the private key is known only by the owner and not by any other party. If this key were compromised for any reason, a fraudulent web user (or website) could decrypt the stream containing the symmetric key and the entire data transfer. The most commonly used key exchange algorithm is the Rivest Shamir Adelman (RSA) algorithm.

For SSL, the sender encrypts the symmetric keys with the public key of the receiver to ensure that the private key of the receiver is the only key that can decrypt the transmission.

## Authentication

*Authentication* ensures that one or more devices in the exchange can verify the identity of the other device. For example, assume a client is connecting to an e-commerce website. Before sending sensitive information such as a credit card number, the client verifies that the server is a legitimate e-commerce website. Both the client and the server may need to authenticate themselves to each other before beginning the transaction. In a financial transaction between two banks, both the client and the server must be confident of the other's identity. SSL facilitates this authentication through the use of digital certificates.

Digital certificates are a form of digital identification to prove the identity of the server to the client, or optionally, the client to the server. A certificate ensures that the identification information is correct and that the public key embedded in the certificate actually belongs to that client or server.

A Certificate Authority (CA) issues digital certificates in the context of a PKI, which uses public-key and private-key encryption to ensure security. CAs are trusted authorities who sign certificates to verify their authenticity. Digital certificates contain the following information:

- Details about the owner (the certificate subject)
- Details about CA (the certificate issuer)
- Public key for the certificate's subject
- Certificate validity and expiration dates
- Privileges associated with the certificate

As the certificate issuer, the CA uses a private key to sign the certificate. Upon receiving a certificate, a client uses the issuer's public key to decrypt and verify the certificate signature. This procedure ensures that the certificate was actually issued and signed by an authorized entity.

Public key certificates support *certificate hierarchies*. A CA creates a hierarchy of subsidiary authorities that share in the responsibility of issuing signed certificates. The CA that sits at the head of the hierarchy is known as the *root authority*. Each level in the hierarchy certifies the level below it, creating a hierarchy of trusted relationships known as *certificate chaining*. This process enables an entity that is verifying a certificate to trace the CA certificates back to the root authority, if needed, to find a CA in the hierarchy that it trusts.

A certificate remains valid until it expires or is revoked by the CA. When a CA revokes a certificate, it adds the certificate to a certificate revocation list (CRL) that lists any certificates that it previously issued but no longer considers valid.

Clients or servers connected to the ACE must have trusted certificates from the same CA or from different CAs in a hierarchy of trusted relationships (for example, A trusts B, and B trusts C, therefore, A trusts C).

## Message Integrity

*Message integrity* assures the recipient of a message that the contents of the message have not been tampered with during transit. To ensure message integrity, SSL applies a message digest to the data before transmitting it. A message digest takes an arbitrary-length message and outputs a fixed-length string that is characteristic of the message.

An important property of the message digest is that it is extremely difficult to reverse. Simply appending a digest of the message to itself before sending it is not enough to guarantee integrity. An attacker can change the message and then change the digest accordingly.

Each message exchanged between peers is protected by a message authentication code (MAC), which can be calculated by using a hash algorithm such as SHA or MD5. The MAC is a hash value of several pieces of data, including a secret value, the actual data being sent, and a sequence number. The secret value is the write session key. The sequence number is a 32-bit counter value. This data is processed by the hash algorithm to derive the MAC. Upon receipt of a message, the receiver verifies the MAC by using the read session key and the predicted sequence number and calculates the hash over the received data. If the two hash values do not match, the data stream has been modified in some way.

## SSL Handshake

The client and server use the SSL handshake protocol to establish an SSL session between the two devices. During the handshake, the client and server negotiate the SSL parameters that they will use during the secure session. [Figure 1-1](#) shows the client/server actions that occur during the SSL handshake.

---

**Note**

The ACE does not replicate SSL and other terminated (proxied) connections from the active context to the standby context.

---

Figure 1-1 SSL Handshake

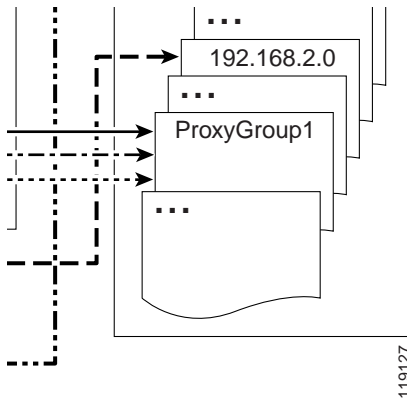

Table 1-1 describes the actions that take place between the client and the server during the SSL handshake.

Table 1-1 SSL Handshake Actions

Step	Message	Action
1	ClientHello	Client initiates the handshake by sending the ClientHello message that proposes the SSL parameters to use during the SSL session.
2	ServerHello	Server responds with the ServerHello message that contains the SSL parameters that it selects for use during the SSL session.
3	Certificate	Server sends the client its public key certificate.
4	ServerHelloDone	Server concludes its part of the SSL negotiations.
5	ClientKeyExchange	Client sends session key information that it encrypts using the server's public key.

**Table 1-1 SSL Handshake Actions (continued)**

Step	Message	Action
6	ChangeCipherSpec	Client instructs the server to activate the negotiated SSL parameters for all future messages that it sends.
7	Finished	Client instructs the server to verify that the SSL negotiation has been successful.
8	ChangeCipherSpec	Server instructs the client to activate the negotiated SSL parameters for all future messages that it sends.
9	Finished	Server instructs the client to verify that the SSL negotiation has been successful.

## ACE SSL Capabilities

Table 1-2 provides information on the SSL capabilities of the ACE.

**Table 1-2 ACE SSL Capabilities**

SSL Feature	Feature Type or Specification Supported by the ACE
SSL versions	<ul style="list-style-type: none"> <li>• SSL Version 3.0 and Transport Layer Security (TLS) Version 1.0</li> <li>• SSL Version 2.0 ClientHello message (hybrid 2/3 hello)</li> </ul>
Public key exchange algorithm	RSA—512 bits, 768 bits, 1024 bits, 1536 bits, 2048 bits
Encryption types	<ul style="list-style-type: none"> <li>• Data Encryption Standard (DES)</li> <li>• Triple-Strength Data Encryption Standard (3DES)</li> <li>• RC4</li> <li>• AES</li> </ul>
Hash types	<ul style="list-style-type: none"> <li>• SSL MAC-MD5</li> <li>• SSL MAC-SHA1</li> </ul>

**Table 1-2 ACE SSL Capabilities (continued)**

SSL Feature	Feature Type or Specification Supported by the ACE
Cipher suites	<ul style="list-style-type: none"> <li>• RSA_WITH_RC4_128_MD5</li> <li>• RSA_WITH_RC4_128_SHA</li> <li>• RSA_WITH_DES_CBC_SHA</li> <li>• RSA_WITH_3DES_EDE_CBC_SHA</li> <li>• RSA_EXPORT_WITH_RC4_40_MD5</li> <li>• RSA_EXPORT_WITH_DES40_CBC_SHA</li> <li>• RSA_EXPORT1024_WITH_RC4_56_MD5</li> <li>• RSA_EXPORT1024_WITH_DES_CBC_SHA</li> <li>• RSA_EXPORT1024_WITH_RC4_56_SHA</li> <li>• RSA_WITH_AES_128_CBC_SHA</li> <li>• RSA_WITH_AES_256_CBC_SHA</li> </ul>
Digital certificates	<p>Supports all major digital certificates from Certificate Authorities (CAs), including the following:</p> <ul style="list-style-type: none"> <li>• VeriSign</li> <li>• Entrust</li> <li>• Netscape iPlanet</li> <li>• Windows 2000 Certificate Server</li> <li>• Thawte</li> <li>• Equifax</li> <li>• Genuity</li> </ul>
Maximum number of certificates	4096
Maximum size of a certificate file	Unlimited (cannot exceed the available capacity of the flash disk)
Maximum number of key pairs	4096

**Table 1-2 ACE SSL Capabilities (continued)**

SSL Feature	Feature Type or Specification Supported by the ACE
Maximum number of SSL concurrent connections	100,000
SSL throughput	1000 Mbps
SSL bulk encryption	1 Gbps
Maximum number of SSL transactions per second (TPS)	By default, the ACE supports 1000 SSL TPS. Installing an optional SSL TPS license allows you to increase the number of TPS that your ACE supports to a maximum of 7,500 TPS. See the <i>Cisco 4700 Series Application Control Engine Appliance Administration Guide</i> guide for information on ACE licensing options.

## ACE SSL Functions

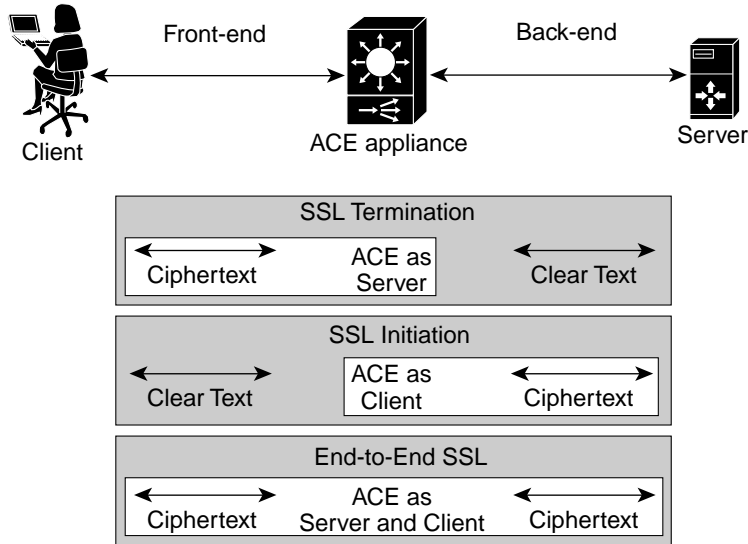

The ACE is responsible for all user authentication, public/private key generation, certificate management, and packet encryption and decryption functions between the client and the server.

You can partition the ACE into multiple contexts (virtual ACE devices). You configure each context with the certificate and key files that the context needs to establish an SSL session with its peer. The ACE creates a secure storage area in flash memory for storing the certificates and keys associated with each context that you create.

To establish and maintain an SSL session between the ACE and its peer, the ACE applies policy maps to the traffic that it receives. When the traffic characteristics match the attributes of a specific policy map, the ACE executes the actions associated with the policy map.

Depending on how you define the policy map, you can configure the ACE to act as a client or a server during an SSL session. [Figure 1-2](#) shows the three basic SSL configurations of the ACE in which the ACE is used to encrypt and decrypt data between the client and the server.

Figure 1-2 ACE SSL Applications

159955

The following sections provide an overview of the three ACE SSL applications:

- [SSL Termination](#)
- [SSL Initiation](#)
- [End-to-End SSL](#)

## SSL Termination

*SSL termination* refers to configuring an ACE context for a front-end application in which the ACE operates as an SSL server that communicates with a client. When you create a Layer 3 and Layer 4 policy map to define the flow between an ACE and a client, the ACE operates as a virtual SSL server by adding security services between a web browser (the client) and the HTTP connection (the server). All inbound SSL flows from a client terminate at the ACE.

After the connection is terminated, the ACE decrypts the ciphertext from the client and sends the data as clear text to an HTTP server. For information about configuring the ACE for SSL termination, see [Chapter 3, Configuring SSL Termination](#).

## SSL Initiation

*SSL initiation* refers to configuring an ACE context for a back-end application in which the ACE operates as a client that communicates with an SSL server. When you create a Layer 7 policy map to define the flow between an ACE and an SSL server, the ACE operates as a client and initiates the SSL session between the ACE and the server. SSL initiation enables the ACE to receive clear text from a client and then to establish an SSL session with an SSL server and join the client connection with the SSL server connection. The ACE encrypts the clear text that it receives from the client and sends the data as ciphertext to an SSL server. The SSL server can either be an ACE configured for SSL termination (virtual SSL server) or a real SSL server (web server).

On the outbound flow from the SSL server, the ACE decrypts the ciphertext from the server and sends clear text back to the client.

For more information on configuring the ACE for SSL initiation, see [Chapter 4, Configuring SSL Initiation](#).

## End-to-End SSL

*End-to-end SSL* refers to configuring an ACE context for both SSL termination and SSL initiation. You can configure the ACE for end-to-end SSL when you have an application that requires establishing a secure SSL channel between the client, the ACE, and the SSL server. For example, a transaction between banks requires end-to-end SSL to protect the financial information exchanged between the client and the server.

End-to-end SSL also allows the ACE to insert load-balancing and security information into the data. The ACE decrypts the ciphertext it receives and inserts the load-balancing and firewall information into the clear text. The ACE then reencrypts the data and passes the ciphertext to its intended destination.

For more information on configuring the ACE for end-to-end SSL initiation, see [Chapter 5, Configuring End-to-End SSL](#).

# ACE SSL Configuration Prerequisites

Before configuring your ACE for SSL operation, you must first configure it for server load balancing (SLB). During the SLB configuration process, you create the following configuration objects:

- Layer 7 class map
- Layer 3 and Layer 4 class map
- Layer 7 policy map
- Layer 3 and Layer 4 policy map

After configuring SLB, modify the existing SLB class maps and policy maps with the SSL configuration requirements described in this guide for SSL termination, SSL initiation, or end-to end SSL.

To configure your ACE for SLB, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## CHAPTER 2

# Managing Certificates and Keys

---

This chapter describes how to use the import and export functions to manage the various certificate and RSA key pair files on the Cisco 4700 Series Application Control Engine (ACE) appliance. This chapter also describes the process for creating and submitting a Certificate Signing Request (CSR), which you use to obtain a certificate from a Certificate Authority (CA).

This chapter contains the following major sections:

- [SSL Digital Certificates and Key Pairs](#)
- [Generating Key Pairs and Certificate Signing Requests](#)
- [Preparing a Global Site Certificate](#)
- [Importing or Exporting Certificate and Key Pair Files](#)
- [Upgrading an SSL Certificate](#)
- [Verifying a Certificate Against a Key Pair](#)
- [Deleting Certificate and Key Pair Files](#)
- [Creating a Chain Group](#)
- [Configuring a Group of Certificates for Authentication](#)

# SSL Digital Certificates and Key Pairs

Digital certificates and key pairs are a form of digital identification for user authentication. CAs, such as VeriSign and Thawte, issue certificates that attest to the validity of the public keys they contain. A client or server certificate includes the following identification attributes:

- Name of the CA (the certificate issuer) and CA digital signature
- Serial number
- Name of the client or server (the certificate subject) that the certificate authenticates
- Subject's public key
- Time stamps that indicate the certificate's expiration date

A CA has one or more signing certificates that it uses for creating SSL certificates and certificate revocation lists (CRLs). Each signing certificate has a matching private key that is used to create the CA signature. The CA makes the signing certificates (with the public key embedded) available to the public, enabling anyone to access and use the signing certificates to verify that an SSL certificate or CRL was actually signed by a specific CA.

The ACE requires certificates and corresponding key pairs for the following applications:

- SSL termination—The ACE acts as an SSL proxy server and terminates the SSL session between it and the client. For SSL termination, you must obtain a server certificate and corresponding key pair.
- SSL initiation—The ACE acts as a client and initiates the SSL session between it and the SSL server. For SSL initiation, a client certificate and corresponding key pair can be used, but is not required unless the SSL server has client authentication enabled.

---

**Note**

The ACE supports wildcard certificates.

---

RSA key pairs are required by an ACE and its peer during the SSL handshake in order for the two devices to establish an SSL session. The key pair refers to a public key and its corresponding private (secret) key. During the handshake, the RSA key pairs are used to encrypt the session key that both devices will use to encrypt the data that follows the handshake.

For more information on the SSL handshake process, see the “[SSL Handshake](#)” section in [Chapter 1, Overview](#).

Before you configure the ACE for SSL termination or SSL initiation, you must import a digital certificate and its corresponding public and private key pair to the desired ACE context.

In a redundant configuration, the ACE does not synchronize the SSL certificates and key pairs that are present in the active context with the standby context of a Fault Tolerant (FT) group. If the ACE performs a configuration synchronization and does not find the necessary certificates and keys on the standby, configuration synchronization fails and the standby context enters the STANDBY\_COLD state.

To copy the certificates and keys to the standby context, you can export the certificates and keys from the active context to an FTP or TFTP server using the **crypto export** command, and then import the certificates and keys to the standby context using the **crypto import** command. You can also import the certificates and keys directly to the standby context using the same method that you used to import the certificates to the active context. This second method is required if the certificates and keys were imported to the active context as non-exportable. For more information about importing and exporting certificates and keys, see the “[Importing or Exporting Certificate and Key Pair Files](#)” section.

To return the standby context to the STANDBY\_HOT state in this case, you must import the necessary SSL certificates and keys to the standby context, and then perform a bulk synchronization of the active context configuration by entering the following commands in configuration mode in the active context of the FT group:

1. **no ft auto-sync running-config**
2. **ft auto-sync running-config**

For more information about redundancy, see the *Cisco 4700 Series Application Control Engine Appliance Administration Guide*.

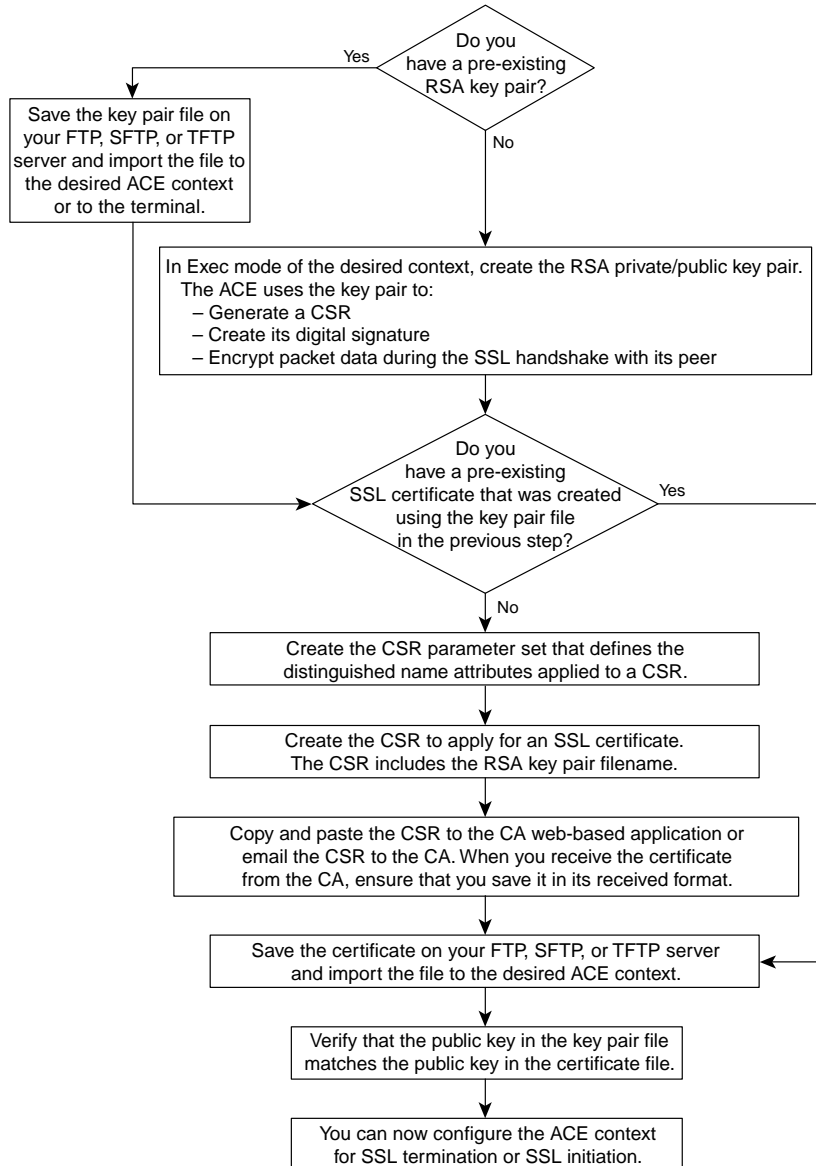

If you do not have a certificate and corresponding key pair, you can use the ACE to generate an RSA key pair of up to 2048 bits and a certificate signing request (CSR). You can create a CSR when you need to apply for a certificate from a CA. The CA signs the CSR and returns the authorized digital certificate to you.

**Note**

To implement strong security policies when generating key pairs or importing certificates and key pairs, you should understand the user roles of the ACE. For more information on user roles, see the *Cisco 4700 Series Application Control Engine Appliance Virtualization Configuration Guide*.

Figure 2-1 provides an overview of how to configure an RSA key pair and SSL certificate for an ACE.

Figure 2-1 *SSL Key and Certificate Configuration Overview*

163358

# Generating Key Pairs and Certificate Signing Requests

If you do not have preexisting certificates and matching key pairs, the ACE includes a series of certificate and key management utilities to generate a key pair or a CSR. When the CA signs your CSR, it becomes the certificate that you can use on the ACE.

If you have preexisting certificates and matching key pairs, you can import them to the desired context on the ACE. For information on importing certificates and private keys, see the [“Importing or Exporting Certificate and Key Pair Files”](#) section.

This section contains the following topics:

- [Generating an RSA Key Pair](#)
- [Creating and Defining a CSR Parameter Set](#)
- [Generating a Certificate Signing Request](#)

## Generating an RSA Key Pair

The ACE supports the generation of RSA key pairs of up to 2048 bits. To generate an RSA key pair, use the **crypto generate key** command in Exec mode.

The syntax of this command is as follows:

```
crypto generate key [non-exportable] bitsize filename
```

The arguments and keywords are as follows:

- **non-exportable**—(Optional) Specifies that the ACE marks the key pair file as nonexportable, which means that you cannot export the key pair file from the ACE.
- *bitsize*—Key pair security strength. The number of bits in the key pair file defines the size of the RSA key pair used to secure web transactions. Longer keys produce a more secure implementation by increasing the strength of the RSA security policy. Available entries (in bits) are as follows:
  - 512 (least security)
  - 768 (normal security)

- 1024 (high security, level 1)
- 1536 (high security, level 2)
- 2048 (high security, level 3)
- *filename*—Name that you assign to the generated RSA key pair file. Enter an unquoted alphanumeric string with a maximum of 40 characters. The key pair filename is used only for identification purposes by the ACE.

For example, to generate the RSA key pair file MYRSAKEY.PEM, enter:

```
host1/Admin# crypto generate key non-exportable 2048 MYRSAKEY.PEM  
Generating 2048 bit RSA key pair  
host1/Admin#
```

After you generate an RSA key pair, you can do the following tasks:

- Create the CSR parameter set—The CSR parameter set defines the distinguished name attributes for the ACE to use during the CSR-generating process. For details on creating a CSR configuration file, see the [“Creating and Defining a CSR Parameter Set”](#) section.
- Generate a CSR for the RSA key pair file and transfer the CSR request to the CA for signing—This action provides an added layer of security because the RSA private key originates directly within the ACE and does not have to be transported externally. Each generated key pair must be accompanied by a corresponding certificate. For details on generating a CSR, see the [“Generating a Certificate Signing Request”](#) section.

## Creating and Defining a CSR Parameter Set

A CSR parameter set defines the *distinguished name* attributes that the ACE applies to the CSR during the CSR-generating process. The distinguished name attributes provide the CA with the information that it needs to authenticate your site. Creating a CSR parameter set allows you to generate multiple CSRs with the same distinguished name attributes.

Each context on the ACE can contain up to eight CSR parameter sets.

This section contains the following topics:

- [Creating a CSR Parameter Set](#)
- [Specifying a Common Name](#)
- [Specifying a Country](#)
- [Specifying a State or Province](#)
- [Specifying a Serial Number](#)
- [Specifying a Locality](#)
- [Specifying an Organization Name](#)
- [Specifying an Organizational Unit](#)
- [Specifying an E-mail Address](#)

## Creating a CSR Parameter Set

You can create a CSR parameter set by using the **crypto csr-params** command in configuration mode. You can create up to eight CSR parameter sets per context.

The syntax of this command is as follows:

```
crypto csr-params csr_param_name
```

The *csr\_param\_name* argument is the name of the CSR parameter set. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to create the CSR parameter set CSR\_PARAMS\_1, enter:

```
host1/Admin(config)# crypto csr-params CSR_PARAMS_1
```

After you create a CSR parameter set, the CLI enters CSR parameter configuration mode, where you define the distinguished name parameters.

```
host1/Admin(config-csr-params)#
```

The distinguished name consists of several required and optional parameters. The ACE requires that you define the following CSR parameter set attributes:

- Country name
- State or province

- Common name

**Note**

If you do not configure the required CSR parameter set attributes, the ACE displays an error message when you try to generate a CSR using the CSR parameter set.

To delete an existing CSR parameter set, enter:

```
host1/Admin(config)# no csr-params CSR_PARAMS_1
```

To display information related to existing CSR parameter sets, use the **show crypto csr-params** command (see [Chapter 6, Displaying SSL Certificate and Key Pair Information](#)).

## Specifying a Common Name

You can define the required common name parameter in the CSR parameter set by using the **common-name** command in CSR parameter configuration mode.

The syntax of this command is as follows:

```
common-name name
```

The *name* argument should be the domain name or individual hostname of the SSL site. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to specify the common name WWW.ABC123.COM, enter:

```
host1/Admin(config-csr-params)# common-name WWW.ABC123.COM
```

To delete an existing common name from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no common-name
```

## Specifying a Country

You can define the required country name parameter in the CSR parameter set by using the **country** command in CSR parameter configuration mode.

The syntax of this command is as follows:

**country** *name*

The *name* argument is the two-character code of the country where the SSL site resides (see the ISO 3166 list of country codes). Enter an unquoted text string with no spaces a maximum of two characters.

For example, to specify the country US (United States), enter:

```
host1/Admin(config-csr-params)# country US
```

To delete an existing country from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no country
```

## Specifying a State or Province

You can define the required state name parameter in the CSR parameter set by using the **state** command in CSR parameter configuration mode.

The syntax of this command is as follows:

**state** *name*

The *name* argument is the name of the state where the SSL site resides. Enter an unquoted text string with no spaces and a maximum of 40 alphanumeric characters.

For example, to specify the state GA (Georgia), enter:

```
host1/Admin(config-csr-params)# state GA
```

To delete an existing state from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no state
```

## Specifying a Serial Number

You can define the required serial number parameter in the CSR parameter set by using the **serial-number** command in CSR parameters configuration mode.

### Note

---

The CA may choose to overwrite the serial number that you provide with their own serial number.

---

The syntax of this command is as follows:

**serial-number** *number*

The *number* argument is the serial number to assign to the certificate. Enter an unquoted text string with no spaces and a maximum of 16 alphanumeric characters.

For example, to specify the serial number 1001, enter:

```
host1/Admin(config-csr-params)# serial-number 1001
```

To delete an existing serial number from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no serial-number
```

## Specifying a Locality

You can define the optional locality parameter in the CSR parameter set by using the **locality** command in CSR parameters configuration mode.

The syntax of this command is as follows:

**locality** *name*

The *name* argument is the locality name to include in the certificate. Enter an unquoted alphanumeric string with no spaces and a maximum of 40 characters.

For example, to specify the locality ATHENS, enter:

```
host1/Admin(config-csr-params)# locality ATHENS
```

To delete an existing locality from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no locality ATHENS
```

## Specifying an Organization Name

You can define the optional organization name parameter in the CSR parameter set by using the **organization-name** command in CSR parameters configuration mode.

The syntax of this command is as follows:

**organization-name** *name*

The *name* argument is the name of the organization to include in the certificate. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to specify the organization ABC123 SYSTEMS INC, enter:

```
host1/Admin(config-csr-params)# organization-name ABC123 SYSTEMS INC
```

To delete an existing organization name from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no organization-name ABC123 SYSTEMS INC
```

## Specifying an Organizational Unit

You can define the optional organization unit parameter in the CSR parameter set by using the **organization-unit** command in CSR parameters configuration mode.

The syntax of this command is as follows:

**organization-unit** *unit*

The *unit* argument is the name of the unit within an organization. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to specify the organization unit SSL ACCELERATOR, enter:

```
host1/Admin(config-csr-params)# organization-unit SSL ACCELERATOR
```

To delete an existing organization unit from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no organization-unit SSL ACCELERATOR
```

## Specifying an E-mail Address

You can define the optional e-mail address parameter in the CSR parameter set by using the **email** command in CSR parameter configuration mode.

The syntax of this command is as follows:

**email** *address*

The *address* argument is the site e-mail address. Enter an unquoted alphanumeric string with no spaces and a maximum of 40 characters.

For example, to specify the e-mail address WEBADMIN@ABC123.COM, enter:

```
host1/Admin(config-csr-params)# email WEBADMIN@ABC123.COM
```

To delete an existing e-mail address from the CSR parameter set, enter:

```
host1/Admin(config-csr-params)# no email
```

## Generating a Certificate Signing Request

You must generate a Certificate Signing Request (CSR) file if you are requesting a new certificate or renewing a certificate. When you submit the generated CSR to a CA, the CA signs the CSR using its RSA private key and the CSR becomes the certificate.

To generate a CSR file for an RSA key pair file and to transfer the certificate request to the CA, use the **crypto generate csr** command in Exec command mode of the context containing the RSA key pair file. This command generates a CSR in PKCS10 encoded in PEM format.

The syntax of this command is as follows:

**crypto generate csr** *csr\_params key\_filename*

The arguments are as follows:

- *csr\_params*—CSR parameter set that contains the distinguished name attributes (see the [“Creating and Defining a CSR Parameter Set”](#) section). Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters. The ACE applies the distinguished name attributes contained in the CSR parameter set to the CSR.

- *key\_filename*—RSA key pair filename that contains the key on which the CSR is built. (This key is the public key that the ACE embeds in the CSR.) Enter an unquoted alphanumeric string with no spaces and a maximum of 40 characters. Ensure that the RSA key pair file is loaded on the ACE for the current context. If the appropriate key pair does not exist, the ACE logs an error message.

For example, to generate a CSR that is based on the CSR parameter set `CSR_PARAMS_1` and the RSA key pair in the file `MYRSAKEY_1.PEM`, enter:

```
host1/Admin# crypto generate csr CSR_PARAMS_1 MYRSAKEY_1.PEM
-----BEGIN CERTIFICATE REQUEST-----
MIIBcDCCARoCAQAwgbQxCzAJBgNVBAYTA1VTMRIwEAYDVQQIEw1Tb211U3RhdGUGx
ETAPBgNVBACcTCFNvbWVudXR5MRcwFQYDVQQKEw5BIENvbXBhbnkgTmFtZTEbMBkG
A1UECzMSV2ViIEFkbWluaXN0cmF0aW9uMR0wGwYDVQQDEXR3d3cuYWNvbXBhbnlu
YW11LmNvbTEpMCCcGCSqGSIb3DQEJARYad2V1YWRtaW5AYWNvbXBhbnluYW11LmNv
bSAwXDAuNjY3ODVtFGREMkHh7s6S1GF131IBWCSe1G4Q/qEztjCO7y3pyjrUvNQIDAQAB
oAAwdQYJKoZIhvcNAQEEBQADQCMMXRdNPBDtMQPFvylpED5UMbeaMRm2iaC+1uZ
IaHmdoX4h5eckauu9pPgSxczau8w68PF+PDS9DAAMeRdxisL
-----END CERTIFICATE REQUEST-----
(config)#
```

The **crypto generate csr** command generates the PKCS10 CSR in PEM format and outputs the CSR to the screen. Most major CAs have web-based applications that require you to cut and paste the certificate request to the screen. If necessary, you can also cut and paste the CSR to a file. The ACE does not save a copy of the CSR locally. You can, however, regenerate the same request again at any time by using the same CSR parameter set and key pair file.

#### Note

If you require a global site certificate that allows 128-bit encryption for export-restricted browsers, you must apply for a StepUp/GSC or chained certificate from the CA. After you receive the certificate, you must prepare it for use with the ACE. For more information, see the [“Preparing a Global Site Certificate”](#) section.

After you submit your CSR to the CA, you will receive your signed certificate in one to seven business days. When you receive your certificate, you must import the certificate to the desired ACE context (see the [“Importing Certificate and Key Pair Files”](#) section).

## Preparing a Global Site Certificate

Export browsers may use 40-bit encryption to initiate connections to SSL servers. With a conventional server certificate, a browser and server complete the SSL handshake and use a 40-bit key to encrypt application data.

A global site certificate is an extended server certificate that allows 128-bit encryption for export-restricted browsers. When the server responds to a browser with a global certificate, the client automatically renegotiates the connection to use 128-bit encryption.

If you applied for a global site certificate from the CA, you must obtain both the global certificate and its intermediate CA certificate. The intermediate CA certificate validates the global certificate. You can obtain a VeriSign Intermediate certificate from the following URL:

<http://www.verisign.com/support/install/intermediate.html>

When you receive your global site certificate and intermediate CA certificate, you must import them to the desired ACE context (see the “[Importing Certificate and Key Pair Files](#)” section). Then you create a certificate chain group that includes both certificates (see the “[Creating a Chain Group](#)” section). The ACE sends the chain group to the client during the initial SSL handshake.

## Importing or Exporting Certificate and Key Pair Files

You can import PEM-encoded certificate and key pair files to the ACE from a remote secure server. To transfer these files, we recommend that you use a secure encrypted transport mechanism between the ACE and the remote server.

The ACE supports the Secure Shell (SSHv2) protocol, which provides secure encryption communications between two hosts over an insecure network. For file transport between network devices, the ACE supports Secure File Transfer Protocol (SFTP), File Transfer Protocol (FTP), and Trivial File Transfer Protocol (TFTP). We recommend that you use SFTP because it is the only one of these three protocols that can provide a secure and encrypted connection.

Before you import a certificate or key pair file to the ACE, you must perform the following tasks:

- On the ACE, ensure that SSH access to the ACE is enabled to accept connections from SSH clients. By default, SSH access is enabled. If you restrict SSH access, the ACE will not accept connections from SSH clients and the import command will fail (an error message will be generated).

---

**Note** For details about configuring the Secure Shell daemon on the Catalyst 6500 series switch or Cisco 7600 series router, see the *Catalyst 6500 Series Switch Cisco IOS Software Configuration Guide* or *Cisco 7600 Series Router Cisco IOS Software Configuration Guide*.

---

- On the SFTP server, verify that the server is properly configured. The user directory must point to the directory where the certificates and key pairs reside. This path is required by the ACE to ensure that certificates and keys are properly copied from or to the SFTP server.

This section contains the following topics:

- [Importing Certificate and Key Pair Files](#)
- [Exporting Certificate and Key Pair Files](#)

## Importing Certificate and Key Pair Files

The ACE supports the importation of PEM-encoded key pairs and certificates (including wildcard certificates) signed by keys of up to and including 2048 bits. You can import a certificate or key pair file to the ACE from a remote server by using the **crypto import** command in Exec mode. Because a network device uses its certificate and corresponding public key together to prove its identity during the SSL handshake, be sure to import both the certificate file and its corresponding key pair file.

The syntax of this command is as follows:

```
crypto import [non-exportable] {ftp | sftp} [passphrase passphrase]
  ip_addr username remote_filename local_filename | {tftp
  [passphrase passphrase] ip_addr remote_filename local_filename } |
terminal local_filename [passphrase passphrase]
```

The keywords, arguments, and options are as follows:

- **non-exportable**—(Optional) Marks the imported file as nonexportable, which means that you cannot export the file from the ACE.
- **ftp**—Specifies the File Transfer Protocol file transfer process.
- **sftp**—Specifies the Secure File Transfer Protocol file transfer process. We recommend that you use SFTP because it is more secure than FTP or TFTP.
- **tftp**—Specifies the Trivial File Transfer Protocol file transfer process.
- **terminal**—Allows you to import a file using cut and paste by pasting the certificate and key pair information to the terminal display. You must use the terminal method to display PEM files, which are in ASCII format.
- **passphrase** *passphrase*—(Optional) Indicates that the file was created with a passphrase, which you must submit with the file transfer request in order to use the file. The passphrase pertains only to encrypted PEM files and PKCS files.
- *ip\_addr*—IP address of the remote server. Enter an IP address in dotted-decimal notation (for example, 192.168.12.15).
- *username*—Username required to access the remote server. The ACE prompts you for your password when you execute the command.
- *remote\_filename*—Name of the certificate or key pair file that resides on the remote server to import.
- *local\_filename*—Name to save the file to when imported to the ACE. Enter an unquoted alphanumeric string with a maximum of 40 characters.

The ACE supports the importation of PEM-encoded SSL certificates and keys with a maximum line width of 130 characters using the terminal. If an SSL certificate or key is not wrapped or it exceeds 130 characters per line, use a text editor such as the visual (vi) editor or Notepad to manually wrap the certificate or key to less than 130 characters per line. Alternatively, you can import the certificate or key by using SFTP, FTP, or TFTP with no regard to line width. Of these methods, we recommend SFTP because it is secure.

For example, to import the RSA key file MYRSAKEY.PEM from an SFTP server, enter:

```
host1/Admin# crypto import non-exportable sftp 1.1.1.1 JOESMITH
/USR/KEYS/MYRSAKEY.PEM MYKEY.PEM
Password: *****
Passive mode on.
Hash mark printing on (1024 bytes/hash mark).
```

```
#
Successfully imported file from remote server.
host1/Admin#
```

The following example shows how to use the **terminal** keyword to allow pasting of the certificate information to the file MYCERT.PEM:

```
host1/Admin# crypto import terminal MYCERT.PEM
Enter PEM formatted data ending with a blank line or "quit" on a line
by itself
-----BEGIN CERTIFICATE-----
MIIC1DCCAj2gAwIBAgIDCCQAMA0GCSqGSIb3DQEBAgUAMIHEMQswCQYDVQQGEwJa
QTEVMBMGAlUECBMMV2VzdGVybiBDYXB1MRItEAYDVQQHEw1DYXB1IFRvd24xHTAb
BgNVBAoTFFRoYXd0ZSBDb25zdWx0aW5nIGNjMSgwJgYDVQQLEx9DZXJ0aWZpY2F0

MSYwJAYJKoZIhvcNAQkBFhdzZXJ2ZXItY2VydHNAZGhhd3R1LmNvbTAeFw0wMTA3
-----END CERTIFICATE-----
quit
```

## Exporting Certificate and Key Pair Files

You can export a certificate or key pair file from the ACE to a remote server or the terminal screen by using the **crypto export** command in Exec command mode.

### Note

You cannot export a certificate or key pair file that you marked as nonexportable when you imported the file to the ACE.

The syntax of this command is as follows:

```
crypto export local_filename {ftp | sftp | tftp | terminal} {ip_addr}
{username} {remote_filename}
```

The keywords, arguments, and options are as follows:

- *local\_filename*—Name of the file that resides on the ACE to export. Enter an unquoted alphanumeric string with a maximum of 40 characters.
- **ftp**—Specifies the File Transfer Protocol file transfer process.
- **sftp**—Specifies the Secure File Transfer Protocol file transfer process. We recommend that you use SFTP because it is more secure than FTP or TFTP.
- **tftp**—Specifies the TFTP Trivial File Transfer Protocol file transfer process.

- **terminal**—Displays the file content on the terminal for copy and paste purposes. Use the **terminal** keyword when you need to cut and paste certificate or private key information from the console. You must use the terminal method to display PEM files, which are in ASCII format.
- *ip\_addr*—IP address or name of the remote server. Enter an IP address in dotted-decimal notation (for example, 192.168.12.15).
- *username*—Username required to access the remote server. The ACE prompts you for your password when you execute the command.
- *remote\_filename*—Name to save the file to on the remote server.

The remote server variables listed after the **terminal** keyword are used by the ACE when you select a transport type of **ftp**, **sftp**, or **tftp** (the variables are not used for **terminal**). If you select one of these transport types and do not define the remote server variables, the ACE prompts you for the variable information.

For example, to use SFTP to export the key file MYKEY.PEM from the ACE to a remote SFTP server, enter:

```
host1/Admin# crypto export MYKEY.PEM sftp 192.168.1.2 JOESMITH
/USR/KEYS/MYKEY.PEM
User password: ****
Writing remote file /usr/keys/mykey.pem
host1/Admin#
```

## Upgrading an SSL Certificate

To upgrade an SSL certificate without disrupting active SSL sessions or pending SSL sessions, use the following steps:

- 
- Step 1** Import the new SSL certificate using the **crypto import** command in Exec mode and save it with a new name. See the [“Importing Certificate and Key Pair Files”](#) section. For example, to import a certificate from an SFTP server, enter the following command:

```
host1/Admin# crypto import non-exportable sftp 1.1.1.1 JOESMITH
/USR/CERTS/MY_CERT.PEM MY_NEW_CERT.PEM
Password: *****
Passive mode on.
Hash mark printing on (1024 bytes/hash mark).
#
Successfully imported file from remote server.
host1/Admin#
```

- Step 2** While the SSL proxy service is actively processing flows, change the certificate file association within the SSL proxy service to the new certificate by using the **cert** command in SSL proxy configuration mode. See the “[Specifying the Certificate](#)” section in [Chapter 3, Configuring SSL Termination](#).
- For example, to associate the certificate in the MY\_NEW\_CERT.PEM certificate file with the PSERVICE\_SERVER SSL proxy service, enter the following commands:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER  
host1/Admin(config-ssl-proxy)# cert MY_NEW_CERT.PEM
```

---

## Verifying a Certificate Against a Key Pair

A digital certificate is built around the public key of a key pair and can only be used with one key pair. You can compare the public key in a certificate file with the public key in a key pair file and verify that they are identical by using the **crypto verify** command in Exec command mode.

### Note

---

If the public key in the certificate does not match the public key in the key pair file, the ACE logs an error message.

---

The syntax of this command is as follows:

```
crypto verify key_filename cert_filename
```

The arguments are as follows:

- *key\_filename*—Name of the context key pair file that the ACE uses to verify against the specified certificate. Enter an unquoted alphanumeric string with a maximum of 40 characters.
- *cert\_filename*—Name of the context certificate file that the ACE uses to verify against the specified key pair. Enter an unquoted alphanumeric string with a maximum of 40 characters.

For example, to verify the public keys in the files MYRSAKEY.PEM and MYCERT.PEM match, enter:

```
host1/Admin# crypto verify myrsakey.pem mycert.pem
keypair in myrsakey.pem matches certificate in mycert.pem
```

The following example shows what the ACE displays when the public keys do not match:

```
host1/Admin# crypto verify myrsakey_2.pem mycert.pem
Keypair in myrsakey_2.pem does not match certificate in mycert.pem
host1/Admin#
```

## Deleting Certificate and Key Pair Files

You can delete certificate and key pair files that are no longer valid by using the **crypto delete** command in Exec command mode.

The syntax of this command is as follows:

```
crypto delete {filename | all}
```

The keywords and arguments are as follows:

- *filename*—Name of a specific certificate or key pair file to delete. Enter an unquoted alphanumeric string with a maximum of 40 characters.
- **all**—Deletes all of the certificate and key pair files from the context.

To display a list of available certificate and key pair files loaded on the ACE, use the **show crypto files** command.

### Note

The **crypto delete** command deletes the specified context crypto files from flash memory; however, existing SSL services are not interrupted. If you do not replace the deleted SSL files, the SSL services are disabled the next time that you enter the **vip inservice** command or when a device reload occurs.

For example, to delete the key pair file MYRSAKEY.PEM, enter:

```
host1/Admin# crypto delete MYRASKEY.PEM
```

# Creating a Chain Group

A chain groups specifies the *certificate chains* that the ACE sends to its peer during the handshake. A certificate chain is a hierarchal list of certificates that includes the subject's certificate, the root CA certificate, and any intermediate CA certificates. Using the information provided in a certificate chain, the certificate verifier can search for a trusted authority in the certificate hierarchal list back to the root CA. The verifier may find what it considers a trusted authority before reaching the root CA certificate, in which case, the verifier stops searching.

When defining an SSL proxy service, you can configure the service with a chain group (see the [“Creating and Defining an SSL Proxy Service”](#) section in [Chapter 3, Configuring SSL Termination](#)).

The ACE supports the following certificate chain group capabilities:

- A chain group can contain up to eight certificate chains.
- Each context on the ACE can contain up to eight chain groups.
- The maximum size of a chain group is 16 KB.

To create a chain group, use the **crypto chaingroup** command in configuration mode.

The syntax of this command is as follows:

```
crypto chaingroup group_name
```

The *group\_name* argument is the name of the chain group. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the chain group MYCHAINGROUP, enter:

```
host1/Admin(config) # crypto chaingroup MYCHAINGROUP
```

After you create a chain group, the CLI enters chaingroup configuration mode, where you add the required certificate files to the group.

```
host1/Admin(config-chaingroup) #
```

To delete an existing chain group, enter:

```
host1/Admin(config) # no crypto chaingroup MYCHAINGROUP
```

You can add certificate files to the chain group by using the **cert** command in chaingroup configuration mode. You can configure a chaingroup with up to nine certificates.

The syntax of this command is as follows:

```
cert cert_filename
```

The *cert\_filename* argument is the name of an existing certificate file stored on the ACE. Enter an unquoted alphanumeric string with a maximum of 40 characters.

**Note**

---

When you make a change to a chain-group certificate, the change takes effect only after you respecify the associated chain group in the SSL proxy service using the **chaingroup** command. See the [“Creating and Defining an SSL Proxy Service”](#) section in [Chapter 3, Configuring SSL Termination](#).

---

To display a list of existing certificate files, use the **show crypto files** command (see the [“Displaying Certificate Information”](#) section in [Chapter 6, Displaying SSL Certificate and Key Pair Information](#)). It is not necessary to add the certificates in any type of hierarchal order because the device that verifies the certificates determines the correct order.

For example, to add the certificate files MYCERTS.PEM and MYCERTS\_2.PEM to the chain group, enter:

```
host1/Admin(config-chaingroup)# cert MYCERTS.PEM  
host1/Admin(config-chaingroup)# cert MYCERTS_2.PEM
```

To remove a certificate file from the chain group, enter:

```
host1/Admin(config-chaingroup)# no cert MYCERTS_2.PEM
```

# Configuring a Group of Certificates for Authentication

On the ACE, you can implement a group of four SSL certificates that are trusted as certificate signers by creating an authentication group. After creating the authentication group and assigning its certificates, you can assign the authentication group to a service in an SSL termination configuration to enable client authentication. For information on client authentication, see the “[Enabling Client Authentication](#)” section in [Chapter 3, Configuring SSL Termination](#).

You can also assign the group to a service in an SSL initiation configuration to allow the ACE to authenticate the server certificate with the group certificates. For information on server authentication, see the “[Using an Authentication Group for Server Authentication](#)” section in [Chapter 4, Configuring SSL Initiation](#).

To create an authentication group and access `authgroup` configuration mode, use the **`crypto authgroup`** command in configuration mode. The syntax of this command is as follows:

```
crypto authgroup group_name
```

The *group\_name* argument is the name of the certificate authentication group. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the authentication group AUTH-CERT1, enter:

```
host1/Admin(config)# crypto authgroup AUTH-CERT1
```

After you create an authentication group, you access `authgroup` configuration mode, where you add the required certificate files to the group.

```
host1/Admin(config-authgroup)#
```

To delete an existing authentication group, enter:

```
host1/Admin(config)# no crypto authgroup AUTH-CERT1
```

To add certificate files to the authentication group, use the **`cert`** command in `authgroup` configuration mode. You can configure an authentication group with up to four certificates.

The syntax of this command is as follows:

```
cert cert_filename
```

The *cert\_filename* argument is the name of an existing certificate file stored on the ACE. Enter an unquoted alphanumeric string with a maximum of 40 characters.

**Note**

---

When you make a change to an authgroup, the change takes effect immediately.

---

To display a list of existing certificate files, use the **show crypto files** command (see the “[Displaying Certificate Information](#)” section in [Chapter 6, Displaying SSL Certificate and Key Pair Information](#)). It is not necessary to add the certificates in any type of hierarchal order because the device verifying the certificates determines the correct order.

For example, to add the certificate files MYCERTS.PEM and MYCERTS\_2.PEM to the authentication group, enter:

```
host1/Admin(config-authgroup)# cert MYCERTS.PEM  
host1/Admin(config-authgroup)# cert MYCERTS_2.PEM
```

To remove a certificate file from the authentication group, enter:

```
host1/Admin(config-authgroup)# no cert MYCERTS_2.PEM
```

# CHAPTER 3

## Configuring SSL Termination

---

This chapter describes the steps required to configure a context on the Cisco 4700 Series Application Control Engine (ACE) appliance as a virtual SSL server for SSL termination. It contains the following major sections:

- [SSL Termination Overview](#)
- [ACE SSL Termination Configuration Prerequisites](#)
- [SSL Termination Configuration Quick Start](#)
- [Creating and Defining an SSL Parameter Map](#)
- [Creating and Defining an SSL Proxy Service](#)
- [Configuring a DNS Client](#)
- [Configuring SSL URL Rewrite](#)
- [Creating a Layer 3 and Layer 4 Class Map for SSL Termination](#)
- [Creating a Layer 3 and Layer 4 Policy Map for SSL Termination](#)
- [Applying the Policy Map to the VLANs](#)
- [Example of an SSL Termination Configuration](#)

# SSL Termination Overview

SSL termination occurs when the ACE, acting as an SSL proxy server, terminates an SSL connection from a client and then establishes a TCP connection to an HTTP server. When the ACE terminates the SSL connection, it decrypts the ciphertext from the client and transmits the data as clear text to an HTTP server.

Figure 3-1 shows the following network connections in which the ACE terminates the SSL connection with the client:

- Client to ACE—SSL connection between a client and the ACE acting as an SSL proxy server
- ACE to Server—TCP connection between the ACE and the HTTP server

**Figure 3-1** SSL Termination with a Client

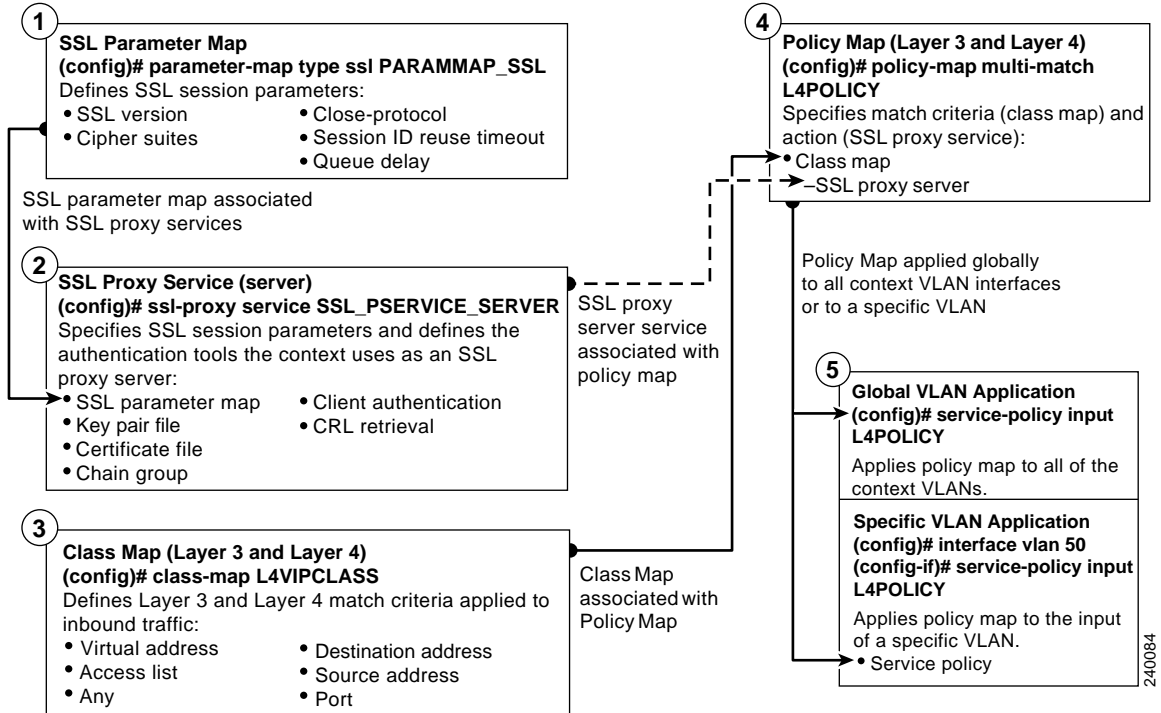

The ACE uses parameter maps, SSL proxy services, and class maps to build the policy maps that determine the flow of information between the client, the ACE, and the server. SSL termination is a Layer 3 and Layer 4 application because it is based on the destination IP addresses of the inbound traffic flow from the client. For this type of application, you create a Layer 3 and Layer 4 policy map that the ACE applies to the inbound traffic.

When configuring a policy map for SSL termination, you associate a parameter map and SSL proxy server service with the policy map to define the SSL session parameters and client/server authentication tools, such as the certificate and RSA key pair. You also associate a class map with the policy map to define the virtual SSL server IP addresses that the destination IP address of the inbound traffic must match. When a match occurs, the ACE negotiates with the client to establish an SSL connection.

Figure 3-2 provides a basic overview of the process required to build and apply the Layer 3 and Layer 4 policy map that the ACE uses for SSL termination. The figure also shows how you associate the various components of the policy map configuration with each other.

Figure 3-2 Basic SSL Termination Configuration Flow Diagram

# ACE SSL Termination Configuration Prerequisites

Before configuring your ACE for SSL operation, you must first configure it for server load balancing (SLB). During the real server and server farm configuration process, when you associate a real server with a server farm, ensure that you assign an appropriate port number for the real server. The default behavior by the ACE is to automatically assign the same destination port that was used by the inbound connection to the outbound server connection if you do not specify a port.

For example, if the incoming connection to the ACE is a secure client HTTPS connection, the connection is typically made on port 443. If you do not assign a port number to the real server, the ACE will automatically use port 443 to connect to the server, which results in the ACE making a clear-text HTTP connection over port 443. In this case, you would typically define an outbound destination port of 80, 81, or 8080 for the back-end server connection.

During the SLB traffic policy configuration process, you create the following configuration objects:

- Layer 7 class map
- Layer 3 and Layer 4 class map
- Layer 7 policy map
- Layer 3 and Layer 4 policy map

After configuring SLB, you modify the existing SLB class maps and policy maps with the SSL configuration requirements described in this guide for SSL termination.

To configure your ACE for SLB, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## SSL Termination Configuration Quick Start

[Table 3-1](#) provides a quick overview of the steps required to configure the ACE for SSL termination. Each step includes the CLI command or a reference to the procedure required to complete the task. For a complete description of each feature and all the options associated with the CLI commands, see the sections following [Table 3-1](#).

**Note**

The following quick start does not include a procedure for creating a parameter map as shown in [Figure 3-2](#). The ACE uses the default parameter map settings as described in [Table 3-2](#).

**Table 3-1** *SSL Termination Configuration Quick Start*

**Task and Command Example**

1. If you are operating in multiple contexts, observe the CLI prompt to verify that you are operating in the desired context. If necessary, log directly in to, or change to, the correct context.

```
host1/Admin# changeto C1  
host1/C1#
```

The rest of the examples in this table use the Admin context. For details on creating contexts, see the *Cisco 4700 Series Application Control Engine Appliance Virtualization Configuration Guide*.

2. Enter configuration mode.

```
host1/Admin# config  
host1/Admin(config)#
```

3. Create an SSL proxy server service to define the handshake parameters that the ACE, acting as an SSL server, applies to a policy map.

```
host1/Admin(config)# ssl-proxy service SSL_PSERVICE_SERVER  
host1/Admin(config-ssl-proxy)#
```

4. Configure the SSL proxy server service by defining the certificate and corresponding RSA key pair.

```
host1/Admin(config-ssl-proxy)# key MYRSAKEY_SERVER  
host1/Admin(config-ssl-proxy)# cert MYCERT_SERVER  
host1/Admin(config-ssl-proxy)# exit  
host1/Admin(config)#
```

**Table 3-1** *SSL Termination Configuration Quick Start (continued)***Task and Command Example**

5. Create a Layer 3 and Layer 4 class map and configure it with the input traffic match criteria as required.

```
host1/Admin(config)# class-map L4VIPCLASS
host1/Admin(config-cmap)# match virtual-address 192.168.10.24 tcp any
host1/Admin(config-cmap)# exit
host1/Admin(config)#
```

6. Create a policy map and associate the class map created in Step 5 with it.

```
host1/Admin(config)# policy-map multi-match L4POLICY
host1/Admin(config-pmap)# class L4VIPCLASS
host1/Admin(config-pmap-c)#
```

7. Associate the SSL proxy server service created in Step 3 with the policy map.

```
host1/Admin(config-pmap-c)# ssl-proxy server SSL_PSERVICE_SERVER
host1/Admin(config-pmap-c)# exit
host1/Admin(config-pmap)# exit
host1/Admin(config)#
```

8. Apply the policy map to the input traffic of the desired interface as follows:

Apply the policy map globally to all context VLANs.

```
host1/Admin(config)# service-policy input L4POLICY
```

Apply the policy map to a specific VLAN.

```
host1/Admin(config)# interface vlan 50
host1/Admin(config-if)# service-policy input L4POLICY
```

**Table 3-1** *SSL Termination Configuration Quick Start (continued)*

Task and Command Example
<p>9. Display the running configuration to verify the information that you just added is configured properly.</p> <pre>host1/Admin(config-if)# do show running-config</pre>
<p>10. (Optional) Save the configuration changes to flash memory by copying the running configuration to the startup configuration.</p> <pre>host1/Admin(config-if)# do copy running-config startup-config</pre>

## Creating and Defining an SSL Parameter Map

An SSL parameter map defines the SSL session parameters that the ACE applies to an SSL proxy service. Creating an SSL parameter map allows you to apply the same SSL session parameters to different proxy services. [Table 3-2](#) describes each SSL session parameter with its default value.

**Table 3-2** *SSL Session Parameters of an SSL Parameter Map*

SSL Session Parameter	Description	Default Value
Cipher suites	Defines the cipher suites that the ACE supports during the SSL handshake (see <a href="#">Table 3-3</a> for a list of available cipher suites that the ACE supports)	The ACE supports all of the available cipher suites
Authentication-failure ignore	Enables the ACE to ignore expired or invalid server certificates and to continue setting up the back-end connection in an SSL initiation configuration.	Disabled

**Table 3-2** *SSL Session Parameters of an SSL Parameter Map (continued)*

SSL Session Parameter	Description	Default Value
Close-protocol	Defines how the ACE executes close-notify messages	<b>none</b> —The ACE sends a close-notify alert message to its peer when closing a session but has no expectation of receiving one back from the peer
Version	Defines the SSL and TLS versions that the ACE supports during the SSL handshake	The ACE supports versions SSL3 and TLS1
Queue delay time	Defines the amount of time that the ACE keeps packet data from the server before encrypting it for the client	Disabled
Session cache timeout	Defines the amount of time that the SSL session ID remains valid before the ACE requires a new SSL handshake to establish a new SSL session.	Disabled
Expired CRL	Defines whether the ACE rejects all incoming client certificates if the CRL is expired.	Disabled

**Note**

If you want an SSL proxy service to use the default values for the SSL session parameters, you do not need to create an SSL parameter map or associate one with the proxy service. When you do not associate a parameter map with the SSL proxy service, the ACE automatically applies the default values for the session parameters listed in [Table 3-2](#) to the proxy service.

You can create an SSL parameter map by using the **parameter-map type ssl** command in configuration mode.

The syntax of this command is as follows:

```
parameter-map type ssl parammap_name
```

The *parammap\_name* argument is the name of the SSL parameter map. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the SSL parameter map PARAMMAP\_SSL, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL
```

After you create an SSL proxy parameter map, the CLI enters parameter map SSL configuration mode.

```
host1/Admin(config-parammap-ssl)#
```

If you exit out of parameter map SSL configuration mode without defining any of its SSL session parameters, the ACE configures the parameter map with the default values listed in [Table 3-2](#).

To delete an existing SSL parameter map, enter:

```
host1/Admin(config)# no parameter-map type ssl PARAMMAP_SSL
```

This section contains the following topics:

- [Adding a Cipher Suite](#)
- [Ignoring Expired or Invalid Server Certificates](#)
- [Defining the Close-Protocol Behavior](#)
- [Defining the SSL and TLS Version](#)
- [Configuring the SSL Queue Delay](#)
- [Configuring the SSL Session Cache Timeout](#)
- [Rejecting Expired Client Certificates](#)

## Adding a Cipher Suite

The SSL protocol supports a variety of different cryptographic algorithms, or ciphers, for use in operations such as the following:

- Authenticating the server and client to each other
- Transmitting certificates
- Establishing session keys

Clients and servers may support different cipher suites, or sets of ciphers, depending on various factors, such as the version of SSL that they support, company policies regarding acceptable encryption strength, and government restrictions on export of SSL-enabled software. Among its other functions, the SSL handshake protocol determines how the server and client negotiate which cipher suite they will use to authenticate each other, transmit certificates, and establish session keys.

As shown in [Figure 3-3](#), a cipher suite consists of the following three algorithms: key exchange algorithm, data encryption algorithm, and message authentication (hash) algorithm.

**Figure 3-3** *Cipher Suite Algorithms*

### Note

Exportable cipher suites are those cipher suites that are not as strong as some of the other cipher suites (for example, 3DES or RC4 with 128-bit encryption) as defined by U.S. export restrictions on software products. Exportable cipher suites may be exported to most countries from the United States and provide the strongest encryption available for exportable products.

To define each of the cipher suites that you want the ACE to support during a secure session, use the **cipher** command in `ssl parameter-map` configuration mode. The cipher suite that you choose depends on your environment and security requirements and must correlate to the certificates and keys that you have loaded on the ACE.

**Note**

By default, the ACE supports all of the cipher suites listed in [Table 3-3](#). The default setting works only when you do not configure the SSL parameter map with any specific ciphers. To return to using the all cipher suites setting, you must delete each specifically defined cipher from the parameter map by using the **no** form of the command.

The syntax of this command is as follows:

```
cipher cipher_name [priority cipher_priority]
```

The keywords and arguments are as follows:

- *cipher\_name*—Name of the cipher suite that you want the ACE to support. [Table 3-3](#) lists the cipher suites that the ACE supports. Enter one of the supported cipher suites from the table.
- **priority**—(Optional) Assigns a priority level to the cipher suite. The priority level represents the preference ranking of the cipher suite, with 10 being the most preferred and 1 being the least preferred. By default, all configured cipher suites have a priority level of 1. When negotiating which cipher suite to use, the ACE selects from the client list based on the cipher suite configured with the highest priority level. A higher priority level will bias towards the specified cipher suite. For SSL termination applications, the ACE uses the priority level to match cipher suites in the client's ClientHello handshake message. For SSL initiation applications, the priority level represents the order in which the ACE places the cipher suites in its ClientHello handshake message to the server.
- *cipher\_priority*—Priority level of the cipher suite. Enter an integer from 1 to 10. The default is 1.

For example, to add the cipher suite `rsa_with_aes_128_cbc_sha` with a priority 2 level, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# cipher rsa_with_aes_128_cbc_sha  
priority 2
```

Repeat the **cipher** command for each cipher suite that you want to include in the SSL parameter map.

To delete a cipher suite from the SSL parameter map, enter:

```
host1/Admin(config-parammap-ssl)# no cipher rsa_with_aes_128_cbc_sha
```

**Table 3-3** lists the available cipher suites that the ACE supports and indicates which of the supported cipher suites are exportable from the ACE. The table also lists the authentication certificate and encryption key required by each cipher suite.

If you use the default setting in which the ACE implicitly supports all of the cipher suites listed in **Table 3-3** or you explicitly define each cipher suite with equal priority and the client connection uses multiple ciphers, the ACE sends the cipher suites to its peer in the same order as they appear in the table, starting with RSA\_WITH\_RC4\_128\_MD5.

**Caution**

Cipher suites with “export” in the title indicate that they are intended for use outside of the domestic United States and have encryption algorithms with limited key sizes.

**Table 3-3** *SSL Cipher Suites Supported by the ACE*

Cipher Suite	Exportable	Authentication Certificate Used	Key Exchange Algorithm Used
RSA_WITH_RC4_128_MD5	No	RSA certificate	RSA key exchange
RSA_WITH_RC4_128_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_DES_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_3DES_EDE_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_AES_128_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_AES_256_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_EXPORT_WITH_RC4_40_MD5	Yes	RSA certificate	RSA key exchange
RSA_EXPORT1024_WITH_RC4_56_MD5	Yes	RSA certificate	RSA key exchange
RSA_EXPORT_WITH_DES40_CBC_SHA	Yes	RSA certificate	RSA key exchange

Table 3-3 SSL Cipher Suites Supported by the ACE (continued)

Cipher Suite	Exportable	Authentication Certificate Used	Key Exchange Algorithm Used
RSA_EXPORT1024_WITH_DES_CBC_SHA	Yes	RSA certificate	RSA key exchange
RSA_EXPORT1024_WITH_RC4_56_SHA	Yes	RSA certificate	RSA key exchange

## Ignoring Expired or Invalid Server Certificates

You can enable the ACE to ignore expired or invalid server certificates and to continue setting up the back-end connection in an SSL initiation configuration close-notify messages by using the **authentication-failure ignore** command in the parameter map SSL configuration mode. This command allows the ACE to ignore the following nonfatal errors with respect to server certificates:

- Certificate not yet valid
- Certificate has expired
- Unable to get issuer certificate
- Certificate revoked

The syntax of this command is as follows:

### **authentication-failure ignore**

For example, to ignore expired or invalid server certificates, enter:

```
host1/Admin(config)# parameter-map type ssl SSL_PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# authentication-failure ignore
```

To return to the default setting of disabled, use the **no** form of the command:

```
host1/Admin(config-parammap-ssl)# no authentication-failure ignore
```

## Defining the Close-Protocol Behavior

You can configure how the ACE handles the sending of close-notify messages by using the **close-protocol** command in the parameter map SSL configuration mode.

The syntax of this command is as follows:

```
close-protocol { disabled | none }
```

The keywords are as follows:

- **disabled**—Specifies that the ACE does not send a close-notify alert message to its peer when closing a session with no expectation of receiving one back from the peer.
- **none**—Specifies that the ACE sends a close-notify alert message to its peer when closing a session but has no expectation of receiving one back from the peer.

For example, to set **close-protocol** to disabled, enter:

```
host1/Admin(config)# parameter-map type ssl SSL_PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# close-protocol disabled
```

To configure the **close-protocol** command with the default setting of none, use the **no** form of the command:

```
host1/Admin(config-parammap-ssl)# no close-protocol
```

## Defining the SSL and TLS Versions

You can specify the version of the security protocol that the ACE supports during the SSL handshake with its peer by using the **version** command in parameter map SSL configuration mode.

The syntax of this command is as follows:

```
version { all | ssl3 | tls1 }
```

The keywords are as follows:

- **all**—(Default) The ACE supports both SSL Version 3.0 and Transport Layer Security (TLS) Version 1.0.
- **ssl3**—The ACE supports only SSL Version 3.0.

- **tls1**—The ACE supports only TLS Version 1.0.

For example, to specify SSL Version 3.0 for the parameter map, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# version ssl3
```

To remove a security protocol version from the SSL proxy parameter map, enter:

```
host1/Admin(config-parammap-ssl)# no version tls1
```

## Configuring the SSL Queue Delay

The ACE queues packet data from the server before encrypting it for transmission to the client. The ACE empties the data from the queue for encryption when one of the following events occurs:

- The queue reaches 4096 bytes.
- The server sends a TCP-FIN segment.
- The queue delay time on the ACE has passed even though the queue had not reached 4096 bytes.

The queue delay time is the amount of time that the ACE waits before emptying the queued data for encryption. By default, the queue delay timer is disabled. You can set the delay time by using the **queue-delay timeout** command in parameter map SSL configuration mode. The syntax of this command is as follows:

**queue-delay timeout** *milliseconds*

The *milliseconds* argument is the time in milliseconds before the data is emptied from the queue. Enter an integer from 0 to 10000. A value of 0 disables the delay timer, causing the ACE to encrypt data from the server as it arrives and then send the encrypted data to the client.

### Note

---

The queue delay applies only to encrypted data that the ACE sends to the client.

---

For example, to set the queue delay time to 500 milliseconds, enter:

```
host1/Admin(config-parammap-ssl)# queue-delay timeout 500
```

To disable the queue delay timer, enter:

```
host1/Admin(config-parammap-ssl)# no queue-delay timeout
```

## Configuring the SSL Session Cache Timeout

An SSL session ID is created every time that the client and the ACE perform a full SSL key exchange and establish a new master secret key. To quicken the SSL negotiation process between the client and the ACE, the SSL session ID reuse feature allows the ACE to reuse the secret key information in the session cache. On subsequent connections with the client, the ACE reuses the key stored in the cache from the last negotiated session. The ACE can store a maximum of 100,000 SSL session IDs in the session cache.

By default, SSL session ID reuse is disabled on the ACE. You can enable session ID reuse by setting a session cache timeout value for the total amount of time that the SSL session ID remains valid before the ACE requires a full SSL handshake to establish a new session.

You can set the session cache timeout by using the **session-cache timeout** command in parameter map SSL configuration mode. The syntax of this command is as follows:

**session-cache timeout** *seconds*

The *seconds* argument is the time in seconds that the ACE reuses the key stored in the cache before removing the session IDs. Enter an integer from 0 to 72000 (20 hours). By default, session ID reuse is disabled. A value of 0 causes the ACE to remove the session IDs from the cache when the cache is full and to implement the least-recently used (LRU) timeout policy.

For example, to set the session cache timeout to 600 seconds, enter:

```
host1/Admin(config-parammap-ssl)# session-cache timeout 600
```

To disable the timer and allow the SSL full handshake to occur for each new connection with the ACE, enter:

```
host1/Admin(config-parammap-ssl)# no session-cache timeout
```

To clear the session cache information for the context, use the **clear crypto session-cache** command. The syntax of this command is as follows:

**clear crypto session-cache** [**all**]

The **all** optional keyword clears all session cache information for all contexts. This option is available in the Admin context only.

## Rejecting Expired Client Certificates

When you configure Certificate Revocation Lists (CRLs) on the ACE for client authentication, as described in the “Using CRLs for Client Authentication” section, the CRLs contain an update field that specifies the date when a new version would be available. By default, the ACE continues to use CRLs that contains an update field with an expired date and, thus, does not reject incoming client certificates using the CRL.

To configure the ACE to reject a client certificate when the CRL in use has expired, use the **expired-crl reject** command in parameter map SSL configuration mode. The syntax of this command is as follows:

### **expired-crl reject**

For example, enter:

```
host1/Admin(config-parammap-ssl)# expired-crl reject
```

To reset the default behavior of the ACE accepting a client certificate after the CRL in use has expired, enter:

```
host1/Admin(config-parammap-ssl)# no expired-crl reject
```

## Creating and Defining an SSL Proxy Service

The SSL proxy service defines the SSL parameter map, key pair, certificate, and chain group that the ACE uses during the SSL handshake. For SSL termination, you configure the ACE with an SSL proxy *server* service because the ACE acts as an SSL server.

You can create an SSL proxy server service by using the **ssl-proxy service** command in configuration mode.

The syntax of this command is as follows:

### **ssl-proxy service** *pservice\_name*

The *pservice\_name* argument is the name of the SSL proxy server service. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the SSL proxy server service `PSERVICE_SERVER`, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER
```

After you create an SSL proxy server service, the CLI enters SSL proxy configuration mode.

```
host1/Admin(config-ssl-proxy)#
```

To delete an existing SSL proxy server service, enter:

```
host1/Admin(config)# no ssl-proxy PSERVICE_SERVER
```

This section contains the following topics:

- [Associating an SSL Parameter Map with the SSL Proxy Server Service](#)
- [Specifying the Key Pair](#)
- [Specifying the Certificate](#)
- [Specifying the Certificate Chain Group](#)
- [Enabling Client Authentication](#)
- [Using CRLs for Client Authentication](#)
- [Configuring Downloaded CRLs for Client Authentication](#)

## Associating an SSL Parameter Map with the SSL Proxy Server Service

You can associate an SSL parameter map with the SSL proxy server service by using the **ssl advanced-options** command in SSL proxy configuration mode.

The syntax of this command is as follows:

```
ssl advanced-options parammap_name
```

The *parammap\_name* argument is the name of an existing SSL parameter map (see the “[Creating and Defining an SSL Parameter Map](#)” section). Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to associate the parameter map `PARAMMAP_SSL` with the SSL proxy service, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER
host1/Admin(config-ssl-proxy)# ssl advanced-options PARAMMAP_SSL
```

To remove the association of an SSL parameter map with the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# no ssl advanced-options PARAMMAP_SSL
```

## Specifying the Key Pair

You can specify the key pair that the ACE uses during the SSL handshake for data encryption by using the **key** command in SSL proxy configuration mode.

### Note

---

The public key in the key pair file that you select must match the public key embedded in the certificate that you select (see the [“Specifying the Certificate”](#) section). For information on verifying a public key match, see the [“Verifying a Certificate Against a Key Pair”](#) section in [Chapter 2, Managing Certificates and Keys](#).

---

The syntax of this command is as follows:

```
key key_filename
```

The *key\_filename* argument is the name of an existing key pair file loaded on the ACE. Enter an unquoted alphanumeric string with a maximum of 40 characters.

For example, to specify the private key in the key pair file MYKEY.PEM, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER  
host1/Admin(config-ssl-proxy)# key MYKEY.PEM
```

To delete a private key from the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# no key MYKEY.PEM
```

## Specifying the Certificate

You can specify the certificate the ACE uses during the SSL handshake process to prove its identity by using the **cert** command in SSL proxy configuration mode.

**Note**

The public key embedded in the certificate that you select must match the public key in the key pair file that you select (see the “[Specifying the Key Pair](#)” section). For information on verifying a public key match, see the “[Verifying a Certificate Against a Key Pair](#)” section in [Chapter 2, Managing Certificates and Keys](#).

The syntax of this command is as follows:

```
cert cert_filename
```

The *cert\_filename* argument is the name of an existing certificate file loaded on the ACE. Enter an unquoted alphanumeric string with a maximum of 40 characters.

For example, to specify the certificate in the certificate file MYCERT.PEM, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER  
host1/Admin(config-ssl-proxy)# cert MYCERT.PEM
```

To delete a certificate file from the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# no cert MYCERT.PEM
```

## Specifying the Certificate Chain Group

You can specify the certificate chain that the ACE sends to its peer during the SSL handshake by using the **chaingroup** command in SSL proxy configuration mode. The ACE includes the certificate chain with the certificate that you specified for the SSL proxy service (see the “[Specifying the Certificate](#)” section).

The syntax of this command is as follows:

```
chaingroup group_name
```

The *group\_name* argument is the name of an existing certificate chain group (see the “[Creating a Chain Group](#)” section in [Chapter 2, Managing Certificates and Keys](#)). The maximum size of a chain group is 16 KB. Enter an unquoted alphanumeric string with a maximum of 64 characters.

**Note**

When you make a change to a chain-group certificate, the change takes effect only after you respecify the associated chain group in the SSL proxy service using the **chaingroup** command.

For example, to specify the certificate chain group MYCHAINGROUP, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_SERVER  
host1/Admin(config-ssl-proxy)# chaingroup MYCHAINGROUP
```

To delete a certificate chain group from the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# no chaingroup MYCHAINGROUP
```

## Enabling Client Authentication

During the flow of a normal SSL handshake, the server sends its certificate to the client. The client verifies the identity of the server through the certificate. However, the client does not send any identification of its own to the server. When you enable the client authentication feature on the ACE, the ACE requires that the client sends a certificate to the server. The server then verifies the following information on the certificate:

- A recognized CA issued the certificate.
- The valid period of the certificate is still in effect.
- The certificate signature is valid.
- The CA has not revoked the certificate.

You can specify the certificate authentication group that the ACE uses during the SSL handshake and enable client authentication on this SSL proxy service by using the **authgroup** command in SSL proxy configuration mode. The ACE includes the certificates configured in the group with the certificate that you specified for the SSL proxy service (see the [“Specifying the Certificate”](#) section).

The syntax of this command is as follows:

```
authgroup group_name
```

The *group\_name* argument is the name of an existing certificate authentication group (see the [“Configuring a Group of Certificates for Authentication”](#) section in [Chapter 2, Managing Certificates and Keys](#)). Enter an unquoted alphanumeric string with a maximum of 64 characters.

**Note**

When you enable client authentication on the ACE, a significant performance decrease may occur on the ACE. Additional latency may occur when you configure CRL retrieval (see the [“Using CRLs for Client Authentication”](#) section).

**Note**

When you make a change to an authgroup, the change takes effect only after you respecify the associated authgroup in the SSL proxy service using the **authgroup** command.

For example, to specify the certificate authentication group AUTH-CERT1, enter:

```
host1/Admin(config-ssl-proxy) # authgroup AUTH-CERT1
```

To delete a certificate authentication group from the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy) # no authgroup AUTH-CERT1
```

## Using CRLs for Client Authentication

By default, the ACE does not use certificate revocation lists (CRLs) during client authentication. You can configure the SSL proxy service to use a CRL in one of the following ways:

- The ACE can scan each client certificate for the service to determine if it contains a CRL in the extension and then retrieve the value if it exists.
- The CRL can be downloaded to the ACE (see the [“Configuring Downloaded CRLs for Client Authentication”](#) section).

**Note**

By default, the ACE does not reject client certificates when the CRL in use has passed its update date. To configure the ACE to reject certificates when the CRL is expired, use the **expired-crl reject** command. For more information, see the [“Rejecting Expired Client Certificates”](#) section.

You can determine which CRL information to use for client authentication by using the **crl** command in SSL proxy configuration mode. The syntax of this command is as follows:

```
crl crl_name | best-effort
```

The argument and keyword are as follows:

- *crl\_name*—Name that you assigned to the CRL when you downloaded it with the configuration mode **crypto crl** command. See the “[Configuring Downloaded CRLs for Client Authentication](#)” section.
- **best-effort**—Specifies that the ACE scans each client certificate to determine if it contains a CRL in the extension and then retrieve the value, if it exists.

For example, to enable the CRL1 CRL for client authentication on an SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# crl CRL1
```

To scan the client certificate for CRL information, enter:

```
host1/Admin(config-ssl-proxy)# crl best-effort
```

To disable the use of a downloaded CRL during client authentication, enter:

```
host1/Admin(config-ssl-proxy)# no crl CRL1
```

To disable the use of client certificates for CRL information during client authentication, enter:

```
host1/Admin(config-ssl-proxy)# no crl best-effort
```

## Configuring Downloaded CRLs for Client Authentication

You can configure a CRL that the ACE downloads on the SSL proxy service for client authentication. If the service is not configured on a policy map or the policy map is not active, the ACE does not download the CRL. The ACE downloads the CRL under the following conditions:

- When you first configure the CRL and apply it to an active Layer 4 policy map as an action (see the “[Associating an SSL Proxy Server Service with the Policy Map](#)” section).
- When you reload the ACE.

- When the NextUpdate arrives, as provided within the CRL itself, the ACE reads this information and updates the CRL based on it. The ACE downloads the updated CRL upon the next client authentication request.

You can configure a maximum of four CRLs per context. After you configure the CRL, assign it to an SSL proxy service for client authentication (see the [“Using CRLs for Client Authentication”](#) section).

The ACE translates the hostnames within the CRLs to IP addresses using a Domain Name System (DNS) client that you configure. For details about configuring a DNS client, see the [“Configuring a DNS Client”](#) section.

To configure a downloaded CRL, use the **crypto crl** command in configuration mode. The syntax of this command is as follows:

```
crypto crl crl_name url
```

The arguments are as follows:

- *crl\_name*—Name that you want to assign to the CRL. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.
- *url*—URL where the ACE retrieves the CRL. Enter the URL full path including the CRL filename in an unquoted alphanumeric string with a maximum of 255 characters. Start the URL with the http:// prefix. Only HTTP URLs are supported.

For example, to configure a CRL that you want to name CRL1 from http://crl.verisign.com/class1.crl, enter:

```
host1/Admin(config)# crypto crl CRL1  
http://crl.verisign.com/class1.crl
```

To remove the CRL, enter:

```
host1/Admin(config)# no crypto crl CRL1
```

## Configuring a DNS Client

With the client authentication feature, you can configure a Domain Name System (DNS) client on the ACE to communicate with a DNS server to provide hostname-to-IP-address translation for hostnames in CRLs. For details about client authentication, see the [“Using CRLs for Client Authentication”](#) section.

Before you configure a DNS client on the ACE, ensure that one or more DNS name servers are properly configured and reachable. Otherwise, translation requests (domain lookups) from the DNS client will be discarded. You can configure a maximum of three name servers. The ACE attempts to resolve the hostnames with the configured name servers in order until the translation succeeds. If the translation fails, the ACE reports an error.

For unqualified hostnames (hostnames that do not contain a domain name), you can configure a default domain name or a list of domain names that the ACE can use to perform the following tasks:

- Complete the hostname
- Attempt a host-name-to-IP-address resolution with a DNS server

To display the DNS client configuration, use the **show running-config** command.

This section contains the following topics:

- [Enabling Domain Lookups](#)
- [Configuring a Default Domain Name](#)
- [Configuring a Domain Name Search List](#)
- [Configuring a Domain Name Server](#)

## Enabling Domain Lookups

To enable the ACE to perform a domain lookup (host-to-address translation) with a DNS server, use the **ip domain-lookup** command in configuration mode. By default, this command is disabled. The syntax of this command is as follows:

### **ip domain-lookup**

For example, to enable domain lookups, enter:

```
host1/Admin(config)# ip domain-lookup
```

To return the state of domain lookups to the default value of disabled, enter:

```
host1/Admin(config)# no ip domain-lookup
```

## Configuring a Default Domain Name

The DNS client feature allows you to configure a default domain name that the ACE uses to complete unqualified hostnames. An unqualified hostname is one that does not contain a domain name (any name without a dot). When domain lookups are enabled and a default domain name is configured, the ACE appends a dot (.) and the configured default domain name to the unqualified hostname and attempts a domain lookup.

To configure a default domain name, use the **ip domain-name** command in configuration mode. The syntax of this command is as follows:

```
ip domain-name name
```

The *name* argument is an unquoted text string with no spaces and a maximum of 85 alphanumeric characters.

For example, to specify a default domain name of cisco.com, enter:

```
host1/Admin(config)# ip domain-name cisco.com
```

In the above example, the ACE appends .cisco.com to any unqualified hostname in a CRL before the ACE attempts to resolve the hostname to an IP address using a DNS name server.

To remove the default domain from the configuration, enter:

```
host1/Admin(config)# no ip domain-name cisco.com
```

## Configuring a Domain Name Search List

Instead of configuring a single default domain name, you can configure a domain name search list that the ACE uses to complete unqualified hostnames. The domain name list can contain a maximum of three domain names. If you configure both a domain name list and a default domain name, the ACE uses only the domain name list and not the single default name. After you have enabled domain name lookups and configured a domain name list, the ACE uses each domain name in turn until it can resolve a single domain name into an IP address.

To configure a domain name search list, use the **ip domain-list** command. The syntax of this command is as follows:

```
ip domain-list name
```

The *name* argument is an unquoted text string with no spaces and a maximum of 85 alphanumeric characters.

For example, to configure a domain name list, enter:

```
host1/Admin(config)# ip domain-list cisco.com
host1/Admin(config)# ip domain-list foo.com
host1/Admin(config)# ip domain-list xyz.com
```

To remove a domain name from the list, enter:

```
host1/Admin(config)# no ip domain-list xyz.com
```

## Configuring a Domain Name Server

To translate a hostname to an IP address, you must configure one or more (maximum of three) existing DNS name servers on the ACE. Ping the IP address of each name server before you configure it to ensure that the server is reachable.

To configure a name server, use the **ip name-server** command in configuration mode. The syntax of this command is as follows:

```
ip name-server ip_address
```

The *ip\_address* argument is the IP address of a name server in dotted decimal notation (for example, 192.168.12.15). You can enter up to three name server IP addresses in one command line.

For example, to configure three name servers for the DNS client feature, enter:

```
host1/Admin(config)# ip name-server 192.168.12.15 192.168.12.16
192.168.12.17
```

To remove a name server from the list, enter:

```
host1/Admin(config)# no ip name-server 192.168.12.15
```

# Configuring SSL URL Rewrite

When a client sends encrypted traffic to the ACE in an SSL termination configuration, the ACE terminates the SSL traffic and then sends clear text to the server. Because the server is unaware of the encrypted traffic flowing between the client and the ACE, the server may return to the client a URL in the Location header of HTTP redirect responses (301: Moved Permanently or 302: Found) in the form `http://www.cisco.com` instead of `https://www.cisco.com`. In this case, the client makes a request to the unencrypted insecure URL, even though the original request was for a secure URL. Because the client connection changes to HTTP, the requested data may not be available from the server using a clear text connection.

To solve this problem, the ACE provides SSLURL rewrite, which changes the redirect URL from `http://` to `https://` in the Location response header from the server before sending the response to the client. By using URL rewrite, you can avoid nonsecure HTTP redirects. All client connections to the web server will be SSL, ensuring the secure delivery of HTTPS content back to the client. The ACE uses regular expression matching to determine whether the URL needs rewriting. If a Location response header matches the specified regular expression, the ACE rewrites the URL. In addition, the ACE provides commands to add or change the SSL and the clear port numbers.

This section contains the following topics:

- [Configuring an Action List](#)
- [Defining the SSL URL Rewrite String and Port](#)
- [Associating an Action List with a Layer 7 HTTP Load-balancing Policy Map](#)

## Configuring an Action List

To configure SSL URL rewrite, you must first create a new action list or use an existing action list of type modify. An action list is a named group of related actions that you want the ACE to perform. For example, to create an action list, enter the following command in configuration mode:

```
host1/Admin(config)# action-list type modify http SSL_ACTLIST  
host1/Admin(config-actlist-mod)#
```

For more information about action lists, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## Defining the SSL URL Rewrite String and Port

You can define the SSL URL, SSL port, and clear port for rewrite by using the **ssl url rewrite** command in action list modify configuration mode. The syntax of this command is as follows:

```
ssl url rewrite location expression [clearport number] [sslport number]
```

The arguments, keywords, and options are as follows:

- **location** *expression*—Specifies the rewriting of the URL in the Location response header based on a URL regular expression match. If the URL in the Location header matches the URL regular expression string that you specify, the ACE rewrites the URL from http:// to https:// and rewrites the port number. Enter an unquoted text string with no spaces and a maximum of 255 alphanumeric characters. Alternatively, you can enter a text string with spaces if you enclose the entire string in quotation marks (“”).

The location regex that you enter must be a pure URL (for example, www\.cisco\.com) with no port or path designations. To match a port, use the **sslport** and **clearport** keywords as described later in this section. If you need to match a path, use the HTTP header rewrite feature to rewrite the string. For information about the HTTP header rewrite feature, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

The ACE supports the use of regular expressions for matching data strings. See [Table 3-4](#) for a list of the supported characters that you can use in regular expressions.

---

**Note** When matching data strings, the period (.) and question mark (?) characters do not have a literal meaning in regular expressions. Use the brackets ([ ]) character classes to match these symbols (for example, enter www[.]xyz[.]com instead of www.xyz.com). You can also use a backslash (\) to escape a dot (.) or a question mark (?).

---

- **clearport** *number*—(Optional) Specifies the clear port number to which the ACE translates the SSL port number before sending a server redirect response to the client. Enter an integer from 1 to 65535. The default is 80.

- **sslport number**—(Optional) Specifies the SSL port number from which the ACE translates a clear port number before sending the server redirect response to the client. Enter an integer from 1 to 65535. The default is 443.

For example, to specify SSL URL rewrite for the URL `www.cisco.com` or `www.cisco.net` using the default SSL port of 443 and a clear port of 8080, enter:

```
host1/Admin(config-actlist-mod)# ssl url rewrite location
www\.cisco\. * sslport 443 clearport 8080
```

In the above example, the ACE attempts to perform the following tasks:

- Match all HTTP redirects to `http://www.cisco.com:8080` or `http://www.cisco.net:8080`
- Rewrite the HTTP redirects as `https://www.cisco.com:443` or `https://www.cisco.net:443`
- Forward the HTTP redirects to the client

After you enter the **ssl url rewrite** command, associate the action list with a Layer 3 and Layer 4 policy map. See the [“Associating an Action List with a Layer 7 HTTP Load-balancing Policy Map”](#) section.

**Table 3-4** Special Characters for Matching String Expressions

Convention	Description
.	One of any character.
.*	Zero or more of any character.
\.	Period (escaped).
[charset]	Match any single character from the range.
[^charset]	Do not match any character in the range. All other characters represent themselves.
()	Expression grouping.
(expr1   expr2)	OR of expressions.
(expr)*	0 or more of expression.
(expr)+	1 or more of expression.
expr{m,n}	Repeat the expression between <i>m</i> and <i>n</i> times, where <i>m</i> and <i>n</i> have a range of 1 to 255.

**Table 3-4** Special Characters for Matching String Expressions (continued)

Convention	Description
<code>expr{m}</code>	Match the expression exactly <i>m</i> times. The range for <i>m</i> is from 1 to 255.
<code>expr{m,}</code>	Match the expression <i>m</i> or more times. The range for <i>m</i> is from 1 to 255.
<code>\a</code>	Alert (ASCII 7).
<code>\b</code>	Backspace (ASCII 8).
<code>\f</code>	Form-feed (ASCII 12).
<code>\n</code>	New line (ascii 10).
<code>\r</code>	Carriage return (ASCII 13).
<code>\t</code>	Tab (ASCII 9).
<code>\v</code>	Vertical tab (ASCII 11).
<code>\0</code>	Null (ASCII 0).
<code>\\</code>	Backslash.
<code>\x##</code>	Any ASCII character as specified in two-digit hexadecimal notation.

## Associating an Action List with a Layer 7 HTTP Load-balancing Policy Map

You can associate an action list with a Layer 7 HTTP loadbalancing policy map by using the **action** command in policy map load balance class configuration mode. The syntax of this command is as follows:

**action** *name*

The *name* argument is the identifier of an existing action list. Enter an unquoted text string with a maximum of 64 alphanumeric characters.

For example, to associate an action list for SSL URL rewrite with a Layer 7 HTTP load-balancing policy map, enter:

```
host1/Admin(config)# policy-map type loadbalance http first-match  
L7_POLICY  
host1/Admin(config-pmap-lb)# class L7CLASS  
host1/Admin(config-pmap-lb-c)# action SSL_ACTLIST
```

To disassociate the action list from the policy map, enter:

```
host1/Admin(config-pmap-lb-c)# no action SSL_ACTLIST
```

## Creating a Layer 3 and Layer 4 Class Map for SSL Termination

The class map that you associate with a policy map acts as a filter for traffic that matches the criteria that you specify. For SSL termination, you can define the match criteria based on one or more of the following traffic characteristics:

- Access list
- Virtual IP address
- Source IP address and subnet mask
- Destination IP address and subnet mask
- TCP/UDP port number or port range

You can create a Layer 3 and Layer 4 class map by using the **class-map** command in configuration mode. For details on creating and configuring a Layer 3 and Layer 4 class map, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

# Creating a Layer 3 and Layer 4 Policy Map for SSL Termination

For SSL termination, you configure the ACE so that it is recognized as an SSL server by a client. To accomplish this, you configure a Layer 3 and Layer 4 policy map that the ACE applies to the inbound traffic. The policy map uses the Layer 3 and Layer 4 class map that you associate with it to determine whether the inbound traffic matches the criteria that you specify. When a match is found, the ACE engages the client in the SSL handshake and establishes an SSL session using the parameters that you specify in the associated SSL proxy server service.

This section contains the following topics:

- [Creating a Layer 3 and Layer 4 Policy Map](#)
- [Associating the Layer 3 and Layer 4 Class Map with the Policy Map](#)
- [Associating an SSL Proxy Server Service with the Policy Map](#)

## Creating a Layer 3 and Layer 4 Policy Map

You can create an SSL termination policy map by using the **policy-map** command in configuration mode.

The syntax of this command is as follows:

```
policy-map multi-match policy_name
```

The *policy\_name* argument is the name that you assign to the policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to create the policy map L4POLICY, enter:

```
host1/Admin(config)# policy-map multi-match L4POLICY
```

After you create a policy map, the CLI enters into policy map configuration mode.

```
host1/Admin(config-pmap)#
```

To delete an existing policy map, enter:

```
host1/Admin(config)# no policy-map L4POLICY
```

For information on associating an SSL class map with the policy map, see the [“Associating the Layer 3 and Layer 4 Class Map with the Policy Map”](#) section.

## Associating the Layer 3 and Layer 4 Class Map with the Policy Map

You can associate the Layer 3 and Layer 4 class map with the policy map by using the **class** command in policy map configuration mode.

The syntax of this command is as follows:

```
class class-map
```

The *class-map* argument is the name of an existing class map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to associate the class map L4VIPCLASS with the policy map, enter:

```
host1/Admin(config)# policy-map multi-match L4POLICY  
host1/Admin(config-pmap)# class L4VIPCLASS
```

After you associate a class map with the policy map, the CLI enters into policy-map class-map configuration mode.

```
host1/Admin(config-pmap-c)#
```

To remove the association of a class map to the policy map, enter:

```
host1/Admin(config-pmap)# no class L4VIPCLASS
```

For information on associating an SSL proxy service with the class map, see the [“Associating an SSL Proxy Server Service with the Policy Map”](#) section.

## Associating an SSL Proxy Server Service with the Policy Map

You can associate an SSL proxy server service with the policy map by using the **ssl-proxy server** command in policy map class configuration mode.

The syntax of this command is as follows:

```
ssl-proxy server pservice
```

The *pservice* argument is the name of an existing SSL proxy server service. Enter an unquoted alphanumeric string with a maximum of 64 characters.

For example, to associate the SSL proxy server service `PSERVICE_SERVER` with the policy map, enter:

```
host1/Admin(config)# policy-map multi-match L4POLICY  
host1/Admin(config-pmap)# class L4VIPCLASS  
host1/Admin(config-pmap-c)# ssl-proxy server PSERVICE_SERVER
```

To remove the class map association, enter:

```
host1/Admin(config-pmap-c)# no ssl-proxy server PSERVICE_SERVER
```

# Applying the Policy Map to the VLANs

This section describes how to apply the Layer 3 and Layer 4 policy map to the VLAN traffic. The ACE allows you to apply the policy globally to all VLANs within the current context or to a specific VLAN in the context.

This section contains the following topics:

- [Applying the Policy Map Globally](#)
- [Applying the Policy Map to a Specific VLAN](#)

## Applying the Policy Map Globally

You can globally apply the policy map to all VLANs in the context by using the **service-policy** command in configuration mode.

The syntax of this command is as follows:

```
service-policy input policy_name
```

The *policy\_name* argument is the name of an existing policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to globally apply the policy map L4POLICY to all VLANs in the context, enter:

```
host1/Admin(config)# service-policy input L4POLICY
```

To globally remove the policy from all VLANs, enter:

```
host1/Admin(config)# no service-policy input L4POLICY
```

## Applying the Policy Map to a Specific VLAN

To apply a policy map to a specific VLAN interface, you must enter interface configuration mode by using the **interface** command in configuration mode.

The syntax of this command is as follows:

```
interface vlan vlan
```

The *vlan* argument is the context VLAN number. Enter an integer from 2 to 4094.

For example, to enter interface configuration mode for VLAN 10, enter:

```
host1/Admin(config)# interface vlan 10  
host1/Admin(config-if)#
```

You can apply the policy map to the interface by using the **service-policy** command in interface configuration mode.

The syntax of this command is as follows:

```
service-policy input policy-name
```

The *policy-name* argument is the name of an existing policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to apply the policy map L4POLICY to VLAN 10, enter:

```
host1/Admin(config)# interface vlan 10  
host1/Admin(config-if)# service-policy input L4POLICY
```

To remove the policy from the interface, enter:

```
host1/Admin(config-if)# no service-policy input L4POLICY
```

## Example of an SSL Termination Configuration

The following example illustrates a running configuration of the ACE acting as an SSL proxy server; terminating SSL or TLS connections from a client and then establishing a TCP connection to an HTTP server. When the ACE terminates the SSL or TLS connection, it decrypts the cipher text from the client and transmits the data as clear text to the HTTP server. The SSL termination configuration appears in bold in the example.

```
access-list ACL1 line 10 extended permit ip any any  
  
probe http GEN-HTTP  
  port 80  
  interval 50  
  faildetect 5  
  expect status 200 200
```

### Example of an SSL Termination Configuration

■ Example of an SSL Termination Configuration

# CHAPTER 4

## Configuring SSL Initiation

---

This chapter describes how to configure a context on the Cisco 4700 Series Application Control Engine (ACE) appliance as an SSL client for SSL initiation.

This chapter contains the following major sections:

- [SSL Initiation Overview](#)
- [ACE SSL Initiation Configuration Prerequisites](#)
- [SSL Initiation Configuration Quick Start](#)
- [Creating and Defining an SSL Parameter Map](#)
- [Creating and Defining an SSL Proxy Service](#)
- [Creating a Layer 7 Class Map for SSL Initiation](#)
- [Creating a Layer 7 Policy Map for SSL Initiation](#)
- [Creating a Layer 3 and Layer 4 Class Map for SSL Initiation](#)
- [Creating a Layer 3 and Layer 4 Policy Map for SSL Initiation](#)
- [Applying the Policy Map to the VLANs](#)
- [Example of an SSL Initiation Configuration](#)

# SSL Initiation Overview

SSL initiation occurs when an ACE, acting as an SSL proxy client, initiates and maintains an SSL connection between itself and an SSL server. In this particular application, the ACE receives clear text from an HTTP client, and encrypts and transmits the data as ciphertext to the SSL server. On the reverse side, the ACE decrypts the ciphertext that it receives from the SSL server and sends the data to the client as clear text.

Figure 4-1 shows the following network connections in which the ACE initiates the SSL connection with the SSL server:

- Client to ACE—HTTP connection between the ACE and the client
- ACE to server—SSL connection between a server and the ACE acting as an SSL proxy client

**Figure 4-1** SSL Initiation with an SSL Server

SSL initiation allows you to send clear text between devices within a site for maximum speed, while sending ciphertext through the Internet between sites or to an SSL server for maximum security. For each SSL server or ACE (acting as an SSL proxy server) to which you want to establish an SSL connection from a clear text connection, you must configure an SSL initiation policy service on the ACE that maps to that SSL server or other ACE.

Figure 4-2 shows an SSL initiation flow with another ACE configured for SSL termination. In this case, ACE B acts as a virtual front-end SSL server.

**Figure 4-2** SSL Initiation with a Second ACE Running SSL Termination

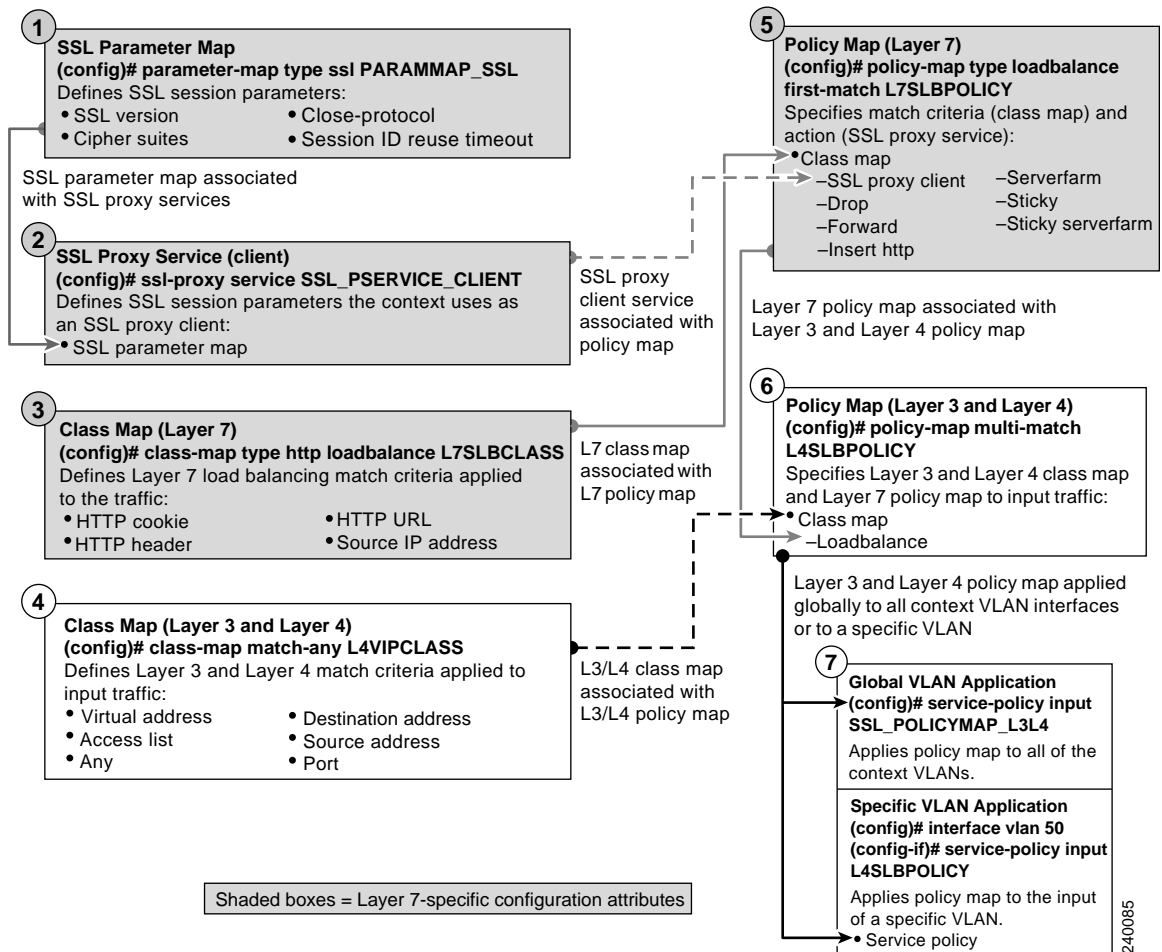

The ACE uses a combination of parameter maps, SSL proxy services, and class maps to build the policy maps that determine the flow of information among the client, the ACE, and the SSL server. For SSL initiation, you configure the ACE so that it is recognized as an SSL client by an SSL server. To accomplish this, you configure the following policy map types:

- **Layer 7 policy map**—This policy map contains an association with a Layer 7 class map and an SSL proxy client service. The class map acts as a traffic filter and looks for traffic that matches the server load-balancing (SLB) criteria that you specify. For SSL initiation, the match criteria is in the form of HTTP load-balancing attributes, such as an HTTP cookie or URL. The SSL proxy client service defines the SSL parameters that the ACE uses during the handshake and subsequent SSL session.
- **Layer 3 and Layer 4 policy map**—You associate the Layer 7 policy map with a Layer 3 and Layer 4 policy map. The ACE applies the Layer 3 and Layer 4 policy map to the context traffic first to determine if the traffic contains specific Layer 3 and Layer 4 match criteria, such as a particular destination, source, or virtual IP address. You specify the match criteria in the Layer 3 and Layer 4 class map that you create and associate with this policy map. When a match is found, the ACE applies the associated Layer 7 policy map to the traffic.

Figure 4-3 provides a basic overview of the process required to build and apply the two types of policy maps that the ACE uses for SSL initiation. The figure also shows how you associate the various components of the policy map configurations with each other.

Figure 4-3 Basic SSL Initiation Configuration Flow Diagram

# ACE SSL Initiation Configuration Prerequisites

Before configuring your ACE for SSL operation, you must first configure it for server load balancing (SLB). During the SLB configuration process, you create the following configuration objects:

- Layer 7 class map
- Layer 3 and Layer 4 class map
- Layer 7 policy map
- Layer 3 and Layer 4 policy map

After configuring SLB, modify the existing SLB class maps and policy maps with the SSL configuration requirements described in this guide for SSL initiation.

To configure your ACE for SLB, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## SSL Initiation Configuration Quick Start

[Figure 4-1](#) provides a quick overview of the steps required to configure the ACE for SSL initiation. Each step includes the CLI command or a reference to the procedure required to complete the task. For a complete description of each feature and all the options associated with the CLI commands, see the sections following [Table 4-1](#).

### Note

---

The following quick start does not include the procedures for creating a parameter map as shown in [Figure 4-3](#). The ACE uses the default parameter map settings as described in [Table 4-2](#).

---

Table 4-1 SSL Initiation Configuration Quick Start

---

**Task and Command Example**

---

1. If you are operating in multiple contexts, observe the CLI prompt to verify that you are operating in the desired context. If necessary, log directly in to, or change to, the correct context.

```
host1/Admin# changeto C1
host1/C1#
```

The rest of the examples in this table use the Admin context. For details on creating contexts, see the *Cisco 4700 Series Application Control Engine Appliance Virtualization Configuration Guide*.

---

2. Enter configuration mode.

```
host1/Admin# config
host1/Admin(config)#
```

---

3. Create an SSL proxy client service to associate with the Layer 7 policy map. For the purposes of this Quick Start, you do not define any parameters of the proxy client service; associating this generic proxy client service with the policy map is all that is required to configure the ACE to perform as an SSL client.

```
host1/Admin(config)# ssl-proxy service SSL_PSERVICE_CLIENT
host1/Admin(config-ssl-proxy)# exit
```

---

4. Create a Layer 7 class map and configure it with the required load-balancing match criteria.

```
host1/Admin(config)# class-map type http loadbalance L7SLBCLASS
host1/Admin(config-cmap-http-lb)# match url XYZ.ORG
host1/Admin(config-cmap-http-lb)# exit
host1/Admin(config)#
```

---

5. Create a Layer 3 and Layer 4 class map and configure it with the required input traffic match criteria.

```
host1/Admin(config)# class-map match-any L4VIPCLASS
host1/Admin(config-cmap)# match virtual-address 192.168.12.2
255.255.255.0
host1/Admin(config-cmap)# exit
host1/Admin(config)#
```

---

**Table 4-1** *SSL Initiation Configuration Quick Start (continued)*

---

**Task and Command Example**

---

6. Create a Layer 7 policy map and associate the Layer 7 class map created in Step 4 with it.

```
host1/Admin(config)# policy-map type loadbalance first-match  
L7SLBPOLICY  
host1/Admin(config-pmap-lb)# class L7SLBCLASS  
host1/Admin(config-pmap-lb-c)#
```

---

7. Associate the SSL proxy client service created in Step 3 with the Layer 7 policy map.

```
host1/Admin(config-pmap-lb-c)# ssl-proxy client  
SSL_PSERVICE_CLIENT  
host1/Admin(config-pmap-lb-c)# exit  
host1/Admin(config-pmap-lb)# exit  
host1/Admin(config)#
```

---

8. Create a Layer 3 and Layer 4 policy map and associate the Layer 3 and Layer 4 class map created in Step 5 with it.

```
host1/Admin(config)# policy-map multi-match L4SLBPOLICY  
host1/Admin(config-pmap)# class CLASSMAP_L3  
host1/Admin(config-pmap-c)#
```

---

9. Associate the load-balancing Layer 7 policy map created in Step 6 with the Layer 3 and Layer 4 policy map.

```
host1/Admin(config-pmap-c)# loadbalance L7SLBPOLICY  
host1/Admin(config-pmap-c)# exit  
host1/Admin(config-pmap)# exit  
host1/Admin(config)#
```

---

**Table 4-1** *SSL Initiation Configuration Quick Start (continued)*

---

**Task and Command Example**

---

10. Apply the Layer 3 and Layer 4 policy map to the input traffic of the desired interface as follows:

Apply the policy map globally to all VLANs in the context.

```
host1/Admin(config)# service-policy input L4SLBPOLICY
```

Apply the policy map to a specific VLAN within the context.

```
host1/Admin(config)# interface vlan 50  
host1/Admin(config-if)# service-policy input L4SLBPOLICY
```

- 
11. Display the running configuration to verify that the information that you just added is configured properly.

```
host1/Admin(config-if)# do show running-config
```

- 
12. (Optional) Save the configuration changes to flash memory by copying the running configuration to the startup configuration.

```
host1/Admin(config-if)# do copy running-config startup-config
```

---

# Creating and Defining an SSL Parameter Map

An SSL parameter map defines the SSL session parameters that the ACE applies to an SSL proxy service. Creating an SSL parameter map allows you to apply the same SSL session parameters to different proxy services. [Table 4-2](#) describes each SSL session parameter with its default value.

**Table 4-2** *SSL Session Parameters of an SSL Parameter Map*

SSL Session Parameter	Description	Default Value
Cipher suites	Defines the cipher suites that the ACE supports during the SSL handshake (see <a href="#">Table 4-3</a> for a list of available cipher suites the ACE supports)	The ACE supports all of the available cipher suites
Authentication-failure ignore	Enables the ACE to ignore expired or invalid server certificates and to continue setting up the back-end connection in an SSL initiation configuration.	Disabled
Close-protocol	Defines how the ACE executes close-notify messages	<b>none</b> —The ACE sends a close notify alert message to the client/server when closing a session but has no expectation of receiving one back from the client/server
Version	Defines the SSL and TLS versions that the ACE supports during the SSL handshake	The ACE supports versions SSL3 and TLS1
Session cache timeout	Defines the amount of time that the SSL session ID remains valid before the ACE requires a new SSL handshake to establish a new SSL session	Disabled

**Note**

If you want an SSL proxy service to use the default values for the SSL session parameters, you do not need to create an SSL parameter map or associate one with the proxy service. When you do not associate a parameter map with the SSL proxy service, the ACE automatically applies the default values for the session parameters listed in [Table 4-2](#) to the proxy service.

The parameter map SSL configuration mode includes the **queue-delay timeout** command. The queue delay applies only to encrypted data that the ACE sends to the client. For this reason, this timer has no effect on SSL initiation connections handled by the ACE.

You can create an SSL parameter map by using the **parameter-map type ssl** command in configuration mode.

The syntax of this command is as follows:

```
parameter-map type ssl parammap_name
```

The *parammap\_name* argument is the name of the SSL parameter map. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the SSL parameter map PARAMMAP\_SSL, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL
```

After you create an SSL proxy parameter map, the CLI enters parameter map SSL configuration mode.

```
host1/Admin(config-parammap-ssl)#
```

If you exit out of the parameter map SSL configuration mode without defining any of its SSL session parameters, the ACE configures the parameter map with the default values listed in [Table 4-2](#).

To delete an existing SSL parameter map, enter:

```
host1/Admin(config)# no parameter-map type ssl PARAMMAP_SSL
```

This section contains the following topics:

- [Adding a Cipher Suite](#)
- [Ignoring Expired or Invalid Server Certificates](#)
- [Ignoring Expired or Invalid Server Certificates](#)
- [Defining the SSL and TLS Versions](#)
- [Configuring the SSL Session Cache Timeout](#)

## Adding a Cipher Suite

The SSL protocol supports a variety of different cryptographic algorithms, or ciphers, for use in operations such as the following:

- Authenticating the server and client to each other
- Transmitting certificates
- Establishing session keys

Clients and servers may support different cipher suites, or sets of ciphers, depending on various factors, such as the version of SSL that they support, company policies regarding acceptable encryption strength, and government restrictions on export of SSL-enabled software. Among its other functions, the SSL handshake protocol determines how the server and client negotiate which cipher suite they will use to authenticate each other, transmit certificates, and establish session keys.

As shown in [Figure 4-4](#), a cipher suite consists of the following three algorithms: key exchange algorithm, data encryption algorithm, and message authentication (hash) algorithm.

Figure 4-4 Cipher Suite Algorithms

**Note**

Exportable cipher suites are those cipher suites that are not as strong as some of the other cipher suites (for example, 3DES or RC4 with 128-bit encryption) as defined by U.S. export restrictions on software products. Exportable cipher suites may be exported to most countries from the United States and provide the strongest encryption available for exportable products.

You can define each of the cipher suites that you want the ACE to support during a secure session by using the **cipher** command in `ssl parameter-map` configuration mode. The cipher suite that you choose depends on your environment and security requirements and must correlate to the certificates and keys that you have loaded on the ACE.

**Note**

By default, the ACE supports all of the cipher suites listed in [Table 4-3](#). The default setting works only when you do not configure the SSL parameter map with any specific ciphers. To return to using the all cipher suites setting, you must delete each specifically defined cipher from the parameter map by using the **no** form of the command.

The syntax of this command is as follows:

```
cipher cipher_name [priority cipher_priority]
```

The keywords and arguments are as follows:

- *cipher\_name*—Name of the cipher suite that you want the ACE to support. [Table 4-3](#) lists the cipher suites that the ACE supports. Enter one of the supported cipher suites from the table.

- **priority**—Assigns a priority level to the cipher suite. The priority level represents the preference ranking of the cipher suite, with 10 being the most preferred and 1 being the least preferred. By default, all configured cipher suites have a priority level of 1. When negotiating which cipher suite to use, the ACE selects from the client list based on the cipher suite configured with the highest priority level. A higher priority level will bias towards the specified cipher suite. For SSL termination applications, the ACE uses the priority level to match cipher suites in the client’s ClientHello handshake message. For SSL initiation applications, the priority level represents the order in which the ACE places the cipher suites in its ClientHello handshake message to the server.
- *cipher\_priority*—Priority level of the cipher suite. Enter a value of 1 to 10. The default priority value is 1.

For example, to add the cipher suite `rsa_with_aes_128_cbc_sha` and assign it a priority 2 level, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL
host1/Admin(config-parammap-ssl)# cipher rsa_with_aes_128_cbc_sha
priority 2
```

Repeat the **cipher** command for each cipher suite that you want to include in the SSL parameter map.

To delete a cipher suite from the SSL parameter map, enter:

```
host1/Admin(config-parammap-ssl)# no cipher rsa_with_aes_128_cbc_sha
```

[Table 4-3](#) lists the available cipher suites that the ACE supports and indicates which of the supported cipher suites are exportable from the ACE. The table also lists the authentication certificate and encryption key required by each cipher suite.

If you use the default setting in which the ACE supports all of the ciphers suites listed in [Table 4-3](#), the ACE sends the cipher suites to its peer in the same order as they appear in the table, starting with `RSA_WITH_RC4_128_MD5`.

**Caution**

---

Cipher suites with “export” in the title indicate that they are intended for use outside of the domestic United States and have encryption algorithms with limited key sizes.

---

Table 4-3 SSL Cipher Suites Supported by the ACE

Cipher Suite	Exportable	Authentication Certificate Used	Key Exchange Algorithm Used
RSA_WITH_RC4_128_MD5	No	RSA certificate	RSA key exchange
RSA_WITH_RC4_128_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_DES_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_3DES_EDE_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_EXPORT_WITH_RC4_40_MD5	Yes	RSA certificate	RSA key exchange
RSA_EXPORT_WITH_DES40_CBC_SHA	Yes	RSA certificate	RSA key exchange
RSA_EXPORT1024_WITH_RC4_56_MD5	Yes	RSA certificate	RSA key exchange
RSA_EXPORT1024_WITH_DES_CBC_SHA	Yes	RSA certificate	RSA key exchange
RSA_EXPORT1024_WITH_RC4_56_SHA	Yes	RSA certificate	RSA key exchange
RSA_WITH_AES_128_CBC_SHA	No	RSA certificate	RSA key exchange
RSA_WITH_AES_256_CBC_SHA	No	RSA certificate	RSA key exchange

## Ignoring Expired or Invalid Server Certificates

You can enable the ACE to ignore expired or invalid server certificates and to continue setting up the back-end connection in an SSL initiation configuration close-notify messages by using the **authentication-failure ignore** command in the parameter map SSL configuration mode. This command allows the ACE to ignore the following nonfatal errors with respect to server certificates:

- Certificate not yet valid
- Certificate has expired
- Unable to get issuer certificate
- Certificate revoked

The syntax of this command is as follows:

**authentication-failure ignore**

For example, to ignore expired or invalid server certificates, enter:

```
host1/Admin(config)# parameter-map type ssl SSL_PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# authentication-failure ignore
```

To return to the default setting of disabled, use the **no** form of the command:

```
host1/Admin(config-parammap-ssl)# no authentication-failure ignore
```

## Defining the Close-Protocol Behavior

You can configure how the ACE handles the sending of close-notify messages by using the **close-protocol** command in the ssl parameter-map configuration mode.

The syntax for this command is as follows:

```
close-protocol { disabled | none }
```

The keywords are as follows:

- **disabled**—Specifies that the ACE does not send a close notify alert message to the client/server when closing a session with no expectation of receiving one back from the client/server.
- **none**—Specifies that the ACE sends a close notify alert message to the client/server when closing a session but has no expectation of receiving one back from the client/server.

For example, to set close-protocol to disabled, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL  
host1/Admin(config-parammap-ssl)# close-protocol disabled
```

To configure the **close-protocol** command to the default setting to send a close notify alert message to the client/server, enter:

```
host1/Admin(config-parammap-ssl)# no close-protocol
```

## Defining the SSL and TLS Versions

You can specify the version of the security protocol that the ACE supports during the SSL handshake with its peer by using the **version** command in parameter map SSL configuration mode.

The syntax of this command is as follows:

```
version { all | ssl3 | tls1 }
```

The keywords are as follows:

- **all**—(Default) The ACE supports both SSL Version 3.0 and TLS Version 1.0.
- **ssl3**—The ACE supports only SSL Version 3.0.
- **tls1**—The ACE supports only TLS Version 1.0.

For example, to specify SSL Version 3.0 for the parameter map, enter:

```
host1/Admin(config)# parameter-map type ssl PARAMMAP_SSL
host1/Admin(config-parammap-ssl)# version ssl3
```

To remove a security protocol version from the SSL proxy parameter map, enter:

```
host1/Admin(config-parammap-ssl)# no version tls1
```

## Configuring the SSL Session Cache Timeout

An SSL session ID is created every time that the client and the ACE perform a full SSL key exchange and establish a new master secret key. To quicken the SSL negotiation process between the client and the ACE, the SSL session ID reuse feature allows the ACE to reuse the secret key information in the session cache. On subsequent connections with the client, the ACE reuses the key stored in the cache from the last negotiated session.

By default, SSL session ID reuse is disabled on the ACE. You can enable session ID reuse by setting a session cache timeout value for the total amount of time that the SSL session ID remains valid before the ACE requires a full SSL handshake to establish a new session.

You can set the session cache timeout by using the **session-cache timeout** command in parameter map SSL configuration mode. The syntax of this command is as follows:

**session-cache timeout** *seconds*

The *seconds* argument is the time in seconds that the ACE reuses the key stored in cache before removing the session IDs. Enter an integer from 0 to 72000 (20 hours). By default, session ID reuse is disabled. A value of 0 causes the ACE to remove the session IDs from the cache when the cache is full and to implement the least-recently used (LRU) timeout policy.

For example, to set the session cache timeout to 600 seconds, enter:

```
host1/Admin(config-parammap-ssl)# session-cache timeout 600
```

To disable the timer and allow the SSL full handshake to occur for each new connection with the ACE, enter:

```
host1/Admin(config-parammap-ssl)# no session-cache timeout
```

To clear the session cache information for the context, use the **clear crypto session-cache** command. The syntax of this command is as follows:

**clear crypto session-cache** [**all**]

The **all** optional keyword clears all session cache information for all contexts. This option is available in the Admin context only.

# Creating and Defining an SSL Proxy Service

The SSL proxy service defines the SSL parameter map that the ACE uses during the SSL handshake. For SSL initiation, you configure the ACE with an SSL proxy *client* service because the ACE acts as an SSL client.

**Note**

You do not need to import or associate keys and certificates in an SSL initiation configuration.

You can create an SSL proxy client service by using the **ssl-proxy service** command in configuration mode.

The syntax of this command is as follows:

```
ssl-proxy service pservice_name
```

The *pservice\_name* argument is the name of the SSL proxy client service. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to create the SSL proxy client service PSERVICE\_CLIENT, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_CLIENT
```

After you create an SSL proxy client service, the CLI enters into SSL proxy configuration mode.

```
host1/Admin(config-ssl-proxy)#
```

To delete an existing SSL proxy client service, enter:

```
host1/Admin(config)# no ssl-proxy PSERVICE_CLIENT
```

This section contains the following topics:

- [Associating an SSL Parameter Map with the SSL Proxy Client Service](#)
- [Using an Authentication Group for Server Authentication](#)

## Associating an SSL Parameter Map with the SSL Proxy Client Service

You can associate an SSL parameter map with the SSL proxy client service by using the **ssl advanced-options** command in SSL proxy configuration mode.

The syntax of this command is as follows:

```
ssl advanced-options parammap_name
```

The *parammap\_name* argument is the name of an existing SSL parameter map (see the “[Creating and Defining an SSL Parameter Map](#)” section). Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

For example, to associate the parameter map PARAMMAP\_SSL with the SSL proxy service, enter:

```
host1/Admin(config)# ssl-proxy service PSERVICE_CLIENT  
host1/Admin(config-ssl-proxy)# ssl advanced-options PARAMMAP_SSL
```

To remove the association of an SSL parameter map with the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy)# no ssl advanced-options PARAMMAP_SSL
```

## Using an Authentication Group for Server Authentication

By default, server authentication is always enabled in an SSL initiation configuration. The server must send a certificate to the ACE. The ACE authenticates the certificate by verifying that it has not expired. However, the ACE does not check that the certificate has been signed by an approved CA. If the server certificate has expired, the ACE rejects the backend connection by sending a reset (RST) to the server. Otherwise, the ACE sets up the SSL connection with the server normally.

An authentication group consists of certificates that are trusted as certificate signers (see the “[Configuring a Group of Certificates for Authentication](#)” section in [Chapter 2, Managing Certificates and Keys](#)). When you assign a group to an SSL-proxy server in an initiation configuration, the ACE enables the checking of the server certificate with the certificates in the group.

**Note**

---

The ACE does not support certificate revocation lists (CRLs) with SSL initiation and server authentication. For information about using CRLs with SSL termination and client authentication, see [Chapter 3, Configuring SSL Termination](#).

---

To use an authentication group for server authentication on this SSL-proxy service, use the **authgroup** command in SSL proxy configuration mode. The syntax of the **authgroup** command is as follows:

```
authgroup group_name
```

The *group\_name* argument is the name of an existing certificate authentication group. Enter an unquoted alphanumeric string with no spaces and a maximum of 64 characters.

**Note**

---

When you enable server authentication, a significant performance decrease of the ACE may occur.

---

For example, to specify the certificate authentication group AUTH-CERT1, enter:

```
host1/Admin(config-ssl-proxy) # authgroup AUTH-CERT1
```

To delete a certificate authentication group from the SSL proxy service, enter:

```
host1/Admin(config-ssl-proxy) # no authgroup AUTH-CERT1
```

## Creating a Layer 7 Class Map for SSL Initiation

The Layer 7 class map that you associate with a policy map acts as a filter for traffic that matches the server load balancing (SLB) criteria that you specify. For SSL initiation, the match criteria is in the form of the following HTTP load-balancing attributes:

- Cookie
- HTTP header
- URL
- Source IP address

You can create a Layer 7 class map by using the **class-map type http loadbalance** command in configuration mode. For details on configuring a Layer 7 class map, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## Creating a Layer 7 Policy Map for SSL Initiation

A Layer 7 policy map enables server load balancing on the ACE. This policy map contains an association with a Layer 7 class map and an SSL proxy client service. To use a Layer 7 SLB policy map, you first create the policy map and then define the **match** statements and policy actions. Because Layer 7 policy maps are child policies, you must associate a Layer 7 policy map with the appropriate Layer 3 and Layer 4 policy map to provide an entry point for Layer 7 SLB traffic classification. You cannot directly apply a Layer 7 policy map to an interface; you can apply only a Layer 3 and Layer 4 policy map to an interface or globally to all interfaces in a context.

This section contains the following topics:

- [Creating a Layer 7 Policy Map](#)
- [Associating a Layer 7 Class Map with the Layer 7 Policy Map](#)
- [Specifying Layer 7 SLB Policy Actions](#)

## Creating a Layer 7 Policy Map

You can create a Layer 7 SLB policy map by using the **policy-map** command in configuration mode.

The syntax of this command is as follows:

```
policy-map type loadbalance first-match map_name
```

The keywords and arguments are as follows:

- **type loadbalance**—Specifies a load-balancing policy map.
- **first-match**—Defines the execution for the Layer 7 load-balancing policy map. The ACE executes only the action specified against the first-matching classification.
- *map\_name*—Identifier assigned to the policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to create the policy map L7SLBPOLICY, enter:

```
host1/Admin(config)# policy-map type loadbalance first-match  
L7SLBPOLICY
```

After you create a Layer 7 policy map, the CLI enters policy map load-balancing configuration mode.

```
host1/Admin(config-pmap-lb)#
```

To delete an existing policy map, enter:

```
host1/Admin(config)# no policy-map L7SLBPOLICY
```

## Associating a Layer 7 Class Map with the Layer 7 Policy Map

You can associate a class map with the policy map by using the **class** command in policy map load-balancing configuration mode.

The syntax of this command is as follows:

```
class { name1 | class-default } [insert-before name2]
```

The keywords, arguments, and options are as follows:

- *name1*—Name of a previously defined traffic class, configured with the **class-map** command, to associate traffic with the traffic policy. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.
- **class-default**—Specifies the reserved, well-known class map created by the ACE. You cannot delete or modify this class. All traffic that fails to meet the other matching criteria in the named class map belongs to the default traffic class. If no specified classification matches the traffic, then the ACE performs the action specified using the **class class-default** command. The **class-default** class map has an implicit **match any** statement in it that enables it to match all traffic.
- **insert-before name2**—(Optional) Places the current class map ahead of an existing class map or match statement specified by the *name2* argument in the policy-map configuration. The ACE does not save the sequence reordering as part of the configuration.

For example, to associate the class map L7SLBCLASS with the policy map, enter:

```
host1/Admin(config-pmap-lb)# class L7SLBCLASS
```

After you associate a class map with the policy map, the CLI enters into policy map load-balancing class configuration mode.

```
host1/Admin(config-pmap-lb-c)#
```

The following example shows how to use the **insert-before** option to define the position of a class map in the policy map:

```
host1/Admin(config-pmap-lb)# class L7SLBCLASS insert-before HTTP_CLASS
host1/Admin(config-pmap-lb-c)#
```

The following example shows how to use the **class class-default** command:

```
host1/Admin(config-pmap-lb)# class class-default
host1/Admin(config-pmap-lb-c)#
```

To remove the association of a class map with the policy map, enter:

```
(config-pmap-lb)# no class L7SLBCLASS
```

## Specifying Layer 7 SLB Policy Actions

After you associate a Layer 7 SLB class map with a Layer 7 SLB policy map or specify inline **match** commands, you need to specify one or more of the following actions that the ACE should take when network traffic matches a class map or inline **match** command:

- Discard requests
- Forward Requests without load balancing
- Enable HTTP header information
- Enable load balancing to a server farm
- Configure a sticky server farm
- Specify the IP differentiated services code point of packets
- Associate an SSL proxy service

This section describes the process of associating an SSL proxy service with the policy map. For details on configuring additional policy actions, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

You can associate an SSL proxy client service with the policy map by using the **ssl-proxy** command in policy map load-balancing class configuration mode.

The syntax of this command is as follows:

**ssl-proxy client** *name*

The *name* argument is the identifier of an existing SSL proxy client service. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to associate the SSL client proxy service PSERVICE\_CLIENT with the class map, enter:

```
host1/Admin(config)# policy-map type loadbalance first-match
L7SLBPOLICY
host1/Admin(config-pmap-lb)# class L7SLBCLASS
host1/Admin(config-pmap-lb-c)# ssl-proxy client PSERVICE_CLIENT
```

To remove the association of the SSL client proxy service to the class map, enter:

```
host1/Admin(config-pmap-lb-c)# no ssl-proxy client PSERVICE_CLIENT
```

# Creating a Layer 3 and Layer 4 Class Map for SSL Initiation

The Layer 3 and Layer 4 class map that you associate with a Layer 3 and Layer 4 policy map acts as a filter for traffic that matches the criteria that you specify. For SSL initiation, you can define the match criteria based on one or more of the following traffic characteristics:

- Access list
- Virtual IP address
- Source IP address and subnet mask
- Destination IP address and subnet mask
- TCP/UDP port number or port range

You can create a Layer 3 and Layer 4 class map by using the **class-map** command in the configuration mode. For details on creating and configuring a Layer 3 and Layer 4 class map, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

# Creating a Layer 3 and Layer 4 Policy Map for SSL Initiation

The Layer 3 and Layer 4 policy map that you create for SSL initiation contains an association with the Layer 7 policy map that the ACE uses for load balancing. Because you can apply only a Layer 3 and Layer 4 policy map directly to a context interface, you need to associate the Layer 7 policy map with the Layer 3 and Layer 4 policy map.

This section contains the following topics:

- [Creating a Layer 3 and Layer 4 Policy Map](#)
- [Associating the Layer 3 and Layer 4 Class Map with the Policy Map](#)
- [Associating a Layer 7 Policy Map with the Class Map](#)

## Creating a Layer 3 and Layer 4 Policy Map

You can create a Layer 3 and Layer 4 policy map by using the **policy-map** command in configuration mode.

The syntax of this command is as follows:

```
policy-map multi-match policy_name
```

The *policy\_name* argument is the name that you assign to the policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to create the policy map L4SLBPOLICY, enter:

```
host1/Admin(config)# policy-map multi-match L4SLBPOLICY
```

After you create a policy map, the CLI enters into policy map configuration mode.

```
host1/Admin(config-pmap)#
```

To delete an existing policy map, enter:

```
host1/Admin(config)# no policy-map L4SLBPOLICY
```

For information on associating an SSL class map with the policy map, see the [“Associating a Layer 7 Class Map with the Layer 7 Policy Map”](#) section.

## Associating the Layer 3 and Layer 4 Class Map with the Policy Map

You can associate the Layer 3 and Layer 4 class map with the policy map by using the **class** command in policy map configuration mode.

The syntax of this command is as follows:

```
class class-map
```

The *class-map* argument is the name of an existing class map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to associate the class map L4SLBCLASS with the policy map, enter:

```
host1/Admin(config)# policy-map multi-match L4SLBPOLICY  
host1/Admin(config-pmap)# class L4SLBCLASS
```

After you associate a class map with the policy map, the CLI enters policy map class configuration mode.

```
host1/Admin(config-pmap-c)#
```

To remove the association of a class map to the policy map, enter:

```
host1/Admin(config-pmap)# no class L4SLBCLASS
```

## Associating a Layer 7 Policy Map with the Class Map

You can associate a Layer 7 policy map with the Layer 3 and Layer 4 class map by using the **loadbalance** command in policy map class configuration mode. This association nests the Layer 7 policy map within the Layer 3 and Layer 4 policy map that the ACE applies directly to the traffic.

The syntax of this command is as follows:

```
loadbalance policy polycymap
```

The **policy** *polycymap* keyword and argument specify the name of an existing Layer 7 policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to associate the Layer 7 policy map L7SLBPOLICY with the class map, enter:

```
host1/Admin(config)# policy-map multi-match L4SLBPOLICY
host1/Admin(config-pmap)# class L4SLBCLASS
host1/Admin(config-pmap-c)# loadbalance policy L7SLBPOLICY
```

To remove the association of the Layer 7 policy map with the class map, enter:

```
host1/Admin(config-pmap-c)# no loadbalance policy L7SLBPOLICY
```

# Applying the Policy Map to the VLANs

This section describes how to apply the Layer 3 and Layer 4 policy map to the VLAN traffic. The ACE allows you to apply the policy globally to all VLANs within the current context or to a specific VLAN in the context.

This section contains the following topics:

- [Applying the Policy Map Globally](#)
- [Applying the Policy Map to a Specific VLAN](#)

## Applying the Policy Map Globally

You can globally apply the policy map to all of the VLANs in the context by using the **service-policy** command in configuration mode.

The syntax of this command is as follows:

```
service-policy input policy_name
```

The *policy\_name* argument is the name of an existing policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to globally apply the policy map L4SLBPOLICY to all of the context VLANs, enter:

```
host1/Admin(config)# service-policy input L4SLBPOLICY
```

To globally remove a policy map from all VLANs, enter:

```
host1/Admin(config)# no service-policy input L4SLBPOLICY
```

## Applying the Policy Map to a Specific VLAN

To apply a policy map to a specific VLAN interface, you must enter interface configuration mode by using the **interface** command in configuration mode.

The syntax of this command is as follows:

```
interface vlan vlan
```

The *vlan* argument is the context VLAN number. Enter an integer from 2 to 4094.

For example, to enter into interface configuration mode for VLAN 10, enter:

```
host1/Admin(config)# interface vlan 10  
host1/Admin(config-if)#
```

You can apply the policy map to the interface by using the **service-policy** command in interface configuration mode.

The syntax of this command is as follows:

```
service-policy input policy-name
```

The *policy-name* argument is the name of an existing policy map. Enter an unquoted text string with no spaces and a maximum of 64 alphanumeric characters.

For example, to apply the policy map L4SLBPOLICY to VLAN 10, enter:

```
host1/Admin(config)# interface vlan 10  
host1/Admin(config-if)# service-policy input L4SLBPOLICY
```

To remove the policy from the interface, enter:

```
host1/Admin(config-if)# no service-policy input L4SLBPOLICY
```

## Example of an SSL Initiation Configuration

The following example illustrates a running configuration of the ACE acting as a SSL proxy client, initiating and maintaining an SSL connection between itself and an SSL server. The ACE receives clear text from an HTTP client, and then encrypts and transmits the data as cipher text to the SSL server. On the reverse side, the ACE decrypts the cipher text that it receives from the SSL server and sends the data to the client as clear text. The SSL initiation configuration appears in bold in the example.

```

# CHAPTER 5

## Configuring End-to-End SSL

---

This chapter describes how to configure a Cisco 4700 Series Application Control Engine (ACE) appliance to provide end-to-end SSL connectivity. This process involves combining SSL termination (front end) with SSL initiation (back end) to provide a secure link between the client, the ACE, and the server. All data is encrypted and sent as ciphertext among the three devices.

This chapter contains the following major sections:

- [End-to-End SSL Overview](#)
- [ACE End-to-End SSL Configuration Prerequisites](#)
- [Configuring End-to-End SSL](#)

## End-to-End SSL Overview

End-to-end SSL refers to the ACE's establishing and maintaining SSL connections between the client at one end of the connection and the server at the other end of the connection. When you configure the ACE for end-to-end SSL, the ACE performs the following functions:

- Terminates an SSL session with the client (front-end connection)
- Initiates an SSL session with the server (back-end connection)
- Load balances the back-end content

End-to-end SSL combines the configurations that you use to configure the ACE for SSL termination and SSL initiation. For end-to-end SSL, you must create the following policy map types:

- Layer 7 policy map—Directs the back-end flow of traffic between the ACE and the server.
- Layer 3 and Layer 4 policy map—Performs the following functions:
  - Directs the front-end flow of traffic between the client and the ACE.
  - Applies the associated Layer 7 policy map to the traffic that meets the criteria of the Layer 3 and Layer 4 policy map.

Figure 5-1 shows an end-to-end SSL application in which the ACE terminates an SSL connection with an SSL client and initiates an SSL connection with an SSL server.

**Figure 5-1** End-to-End SSL

153354

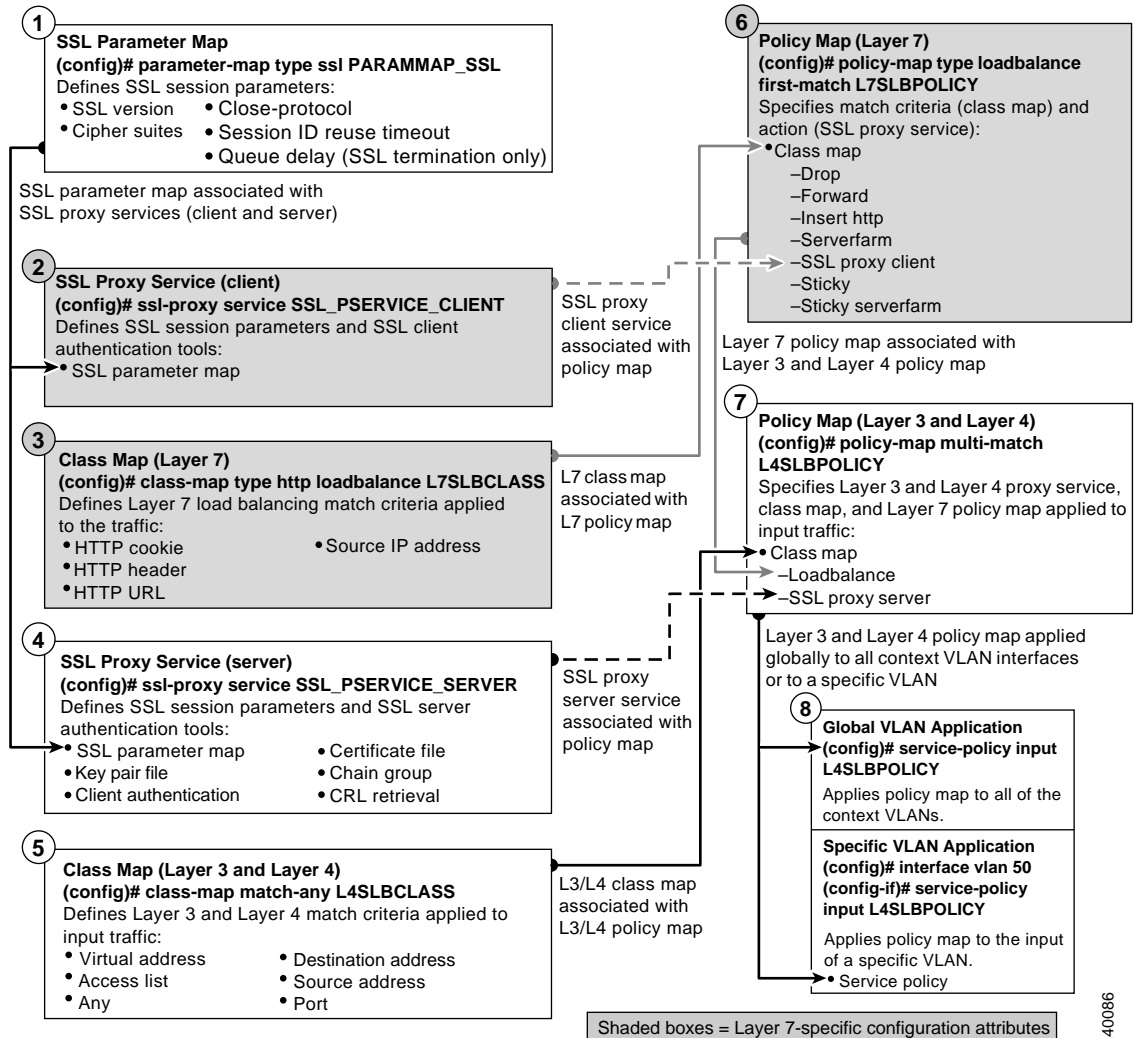

The ACE uses a combination of parameter maps, SSL proxy services, and class maps to build the policy maps that determine the flow of information between the client, the ACE, and the SSL server.

Figure 5-2 provides a basic overview of the process required to build the Layer 7 load-balancing policy map and associate it with the Layer 3 and Layer 4 policy map to create an end-to-end SSL configuration. To allow you to easily discern between the Layer 7 and Layer 3 and Layer 4 configuration attributes, the Layer 7 attributes are shaded gray.

In the final step of the process, you apply the Layer 3 and Layer 4 policy map to the input traffic of the context. The figure also shows how the various components of the policy map configurations are associated with each other.

Figure 5-2 Basic End-to-End SSL Configuration Flow Diagram

240086

# ACE End-to-End SSL Configuration Prerequisites

Before configuring your ACE for SSL operation, you must first configure it for server load balancing (SLB). During the SLB configuration process, you create the following configuration objects:

- Layer 7 class map
- Layer 3 and Layer 4 class map
- Layer 7 policy map
- Layer 3 and Layer 4 policy map

After configuring SLB, modify the existing SLB class maps and policy maps with the SSL configuration requirements described in this guide for end-to end SSL.

To configure your ACE for SLB, see the *Cisco 4700 Series Application Control Engine Appliance Server Load-Balancing Configuration Guide*.

## Configuring End-to-End SSL

[Table 5-1](#) provides an overview of the process required to configure the ACE for end-to-end SSL. Because end-to-end SSL combines the configuration processes of SSL termination and SSL initiation, the procedure provides links to the sections of this guide where the specified process is described in detail.

**Table 5-1** *End-to-End SSL Configuration Quick Start*

---

### Task

---

1. Configure the ACE for SSL initiation as described in [Chapter 4, Configuring SSL Initiation](#). The SSL initiation configuration configures all of the back-end operation and a portion of the front-end operation.

Do not apply the configuration to the VLANs at this time.

---

2. Create a parameter map for the ACE to use in the front-end operation as described in the “[Creating and Defining an SSL Parameter Map](#)” section of [Chapter 3, Configuring SSL Termination](#).

Skip this step if the ACE is to use the same parameter map that you created in Step 1 for the back-end operation.

---

**Table 5-1** *End-to-End SSL Configuration Quick Start (continued)*

---

Task
3. Create an SSL proxy server service as described in the “ <a href="#">Creating and Defining an SSL Proxy Service</a> ” section of <a href="#">Chapter 3, Configuring SSL Termination</a> .
4. Associate the SSL proxy server service with the Layer 3 and Layer 4 policy map created in Step 1. For information on making this association, see the “ <a href="#">Associating an SSL Proxy Server Service with the Policy Map</a> ” section of <a href="#">Chapter 3, Configuring SSL Termination</a> .
5. Apply the Layer 3 and Layer 4 policy map to the VLANs as described in the “ <a href="#">Applying the Policy Map to the VLANs</a> ” section of <a href="#">Chapter 3, Configuring SSL Termination</a> .
6. (Optional) Save the configuration changes to flash memory by copying the running configuration to the startup configuration.  <pre>host1/Admin(config-if)# do copy running-config startup-config</pre>

---

## CHAPTER 6

# Displaying SSL Certificate and Key Pair Information

---

This chapter describes how to use the available **show** commands to display SSL-related information, such as the certificate and key pair files loaded on the ACE. The **show** commands display information associated with the context from which you execute the command. Each command described in this chapter also includes an explanation of the command output.

While the **show** commands are Exec mode commands, you can execute a **show** command from any configuration mode by using the **do** command. The following examples show how to execute the **show running-config** command from either Exec mode or configuration mode.

From Exec mode, enter:

```
host1/Admin# show running-config
```

From configuration mode, enter:

```
host1/Admin(config)# do show running-config
```

This chapter contains the following major sections:

- [Displaying CSR Parameter Set Configurations](#)
- [Displaying the List of Certificate and Key Pair Files](#)
- [Displaying Certificate Information](#)
- [Displaying SSL Certificate and Key Pair Information](#)
- [Displaying RSA Key Pair Information](#)

- [Displaying Certificate Chain Group Information](#)
- [Displaying Client Authentication Group Information](#)
- [Displaying Cached TLS and SSL Session Entries](#)
- [Displaying TLS and SSL Statistics](#)

## Displaying CSR Parameter Set Configurations

To display the CSR parameter set summary and detailed reports, use the **show crypto csr-params** command in Exec mode.

The syntax of this command is as follows:

```
show crypto csr-params {params_set | all}
```

The arguments and keywords are:

- *params\_set*— argument is a specific CSR parameter set. Enter an unquoted alphanumeric string with a maximum of 64 characters. The ACE displays the detailed report for the specified CSR parameter set. The detailed report contains the distinguished name attributes of the CSR parameter set.
- To display the summary report that lists all the CSR parameter sets for the current context, enter the command without specifying a CSR parameter set.

For example, to display the CSR parameter set summary report, enter:

```
host1/Admin# show crypto csr-params all
```

The following example shows how to display the detailed report for the MYCSRCONFIG CSR parameter set:

```
host1/Admin# show crypto csr-params MTCSRCONFIG
```

[Table 6-1](#) describes the fields in the **show crypto csr-params** command output.

**Table 6-1** *Field Descriptions for the show crypto csr-params config\_name Command*

Field	Description
Country-name	Country where the certificate owner resides.
State	State where the certificate owner resides.

**Table 6-1** *Field Descriptions for the show crypto csr-params config\_name Command (continued)*

Field	Description
Locality	Locality where the certificate owner resides.
Org-name	Name of the organization (certificate owner or subject).
Org-unit	Name of unit within the organization.
Common-name	Common-name (domain name or individual hostname of the SSL site).
Serial number	Serial number.
Email	E-mail address.

## Displaying the List of Certificate and Key Pair Files

To display a list of all available certificate and key pair files, use the **show crypto files** command in Exec mode.

For example, to display the list of certificate and key pair files, enter:

```
host1/Admin# show crypto files
```

[Table 6-2](#) describes the fields in the **show crypto files** command output.

**Table 6-2** *Field Descriptions for the show crypto files Command*

Field	Description
Filename	Name of the file that contains the certificate or key pair.
Size	Size of the file.
Type	Format of the file: PEM, DER, or PKCS12.

**Table 6-2** *Field Descriptions for the show crypto files Command (continued)*

Field	Description
Exportable	Indicates whether you can export the file from the ACE using the <b>crypto export</b> command: <ul style="list-style-type: none"> <li>• <b>Yes</b>—You can export the file to an FTP, SFTP, or TFTP server (see the “Exporting Certificate and Key Pair Files” section in Chapter 2, “Managing Certificates and Keys”).</li> <li>• <b>No</b>—You cannot export the file as it is protected.</li> </ul>
Key/Cert	Indicates whether the file contains a certificate (CERT), a key pair (KEY), or both (BOTH).

## Displaying Certificate Information

To display the certificate summary and detailed reports, use the **show crypto certificate** command in Exec mode.

The syntax of this command is as follows:

```
show crypto certificate {filename | all}
```

The keywords and arguments are as follows:

- *filename*—Name of a specific certificate file. Enter an unquoted alphanumeric string with a maximum of 40 characters. The ACE displays the certificate detailed report for the specified file. If the certificate file contains a chain, the ACE displays only the bottom level certificate (the signers are not displayed).
- **all**—Displays the certificate summary report that lists all the certificate files for the current context.

For example, to display the certificate summary report, enter:

```
host1/Admin# show crypto certificate all
```

[Table 6-3](#) describes the fields in the **show crypto certificate all** command output.

**Table 6-3** *Field Descriptions for the show crypto certificate all Command*

Field	Description
Certificate file	Name of the certificate file.
Subject	Distinguished name of the organization that owns the certificate and possesses the private key.
Issuer	Distinguished name of the Certificate Association (CA) that issued the certificate.
Not Before	Starting time period, before which the certificate is not considered valid.
Not After	Ending time period, after which the certificate is not considered valid.
CA Cert	Certificate of the CA that signed the certificate.

The following example shows how to display the detailed report for the MYCERT.PEM certificate file:

```
host1/Admin# show crypto certificate MYCERT.PEM
```

**Table 6-4** describes the fields in the `show crypto certificate filename` command output.

**Table 6-4** *Field Descriptions for the show crypto certificate filename Command*

Field	Description
Certificate	Name of the certificate file.
<b>Data</b>	
Version	Version of the X.509 standard. The certificate complies with this version of the standard.
Serial Number	Serial number associated with the certificate.
Signature Algorithm	Digital signature algorithm used for the encryption of information with a public/private key pair.
Issuer	Distinguished name of the CA that issued the certificate.

**Table 6-4** *Field Descriptions for the show crypto certificate filename Command (continued)*

Field	Description
<b>Validity</b>	
Not Before	Starting time period, before which the certificate is not considered valid.
Not After	Ending time period, after which the certificate is not considered valid.
Subject	Distinguished name of the organization that owns the certificate and possesses the private key.
<b>Subject Public Key Info</b>	
Public Key Algorithm	Name of the key exchange algorithm used to generate the public key (for example, RSA).
RSA Public Key	Number of bits in the key to define the size of the RSA key pair used to secure web transactions.
Modulus	Actual public key on which the certificate was built.
Exponent	One of the base numbers used to generate the key.
<b>X509v3 Extensions</b>	Array of X509v3 extensions added to the certificate.
X509v3 Basic Constraints	Indicates whether the subject may act as a CA, with the certified public key being used to verify certificate signatures. If so, a certification path length constraint may also be specified.
Netscape Comment	Comment that may be displayed when the certificate is viewed.
X509v3 Subject Key Identifier	Public key to be certified. It enables distinct keys used by the same subject to be differentiated (for example, as key updating occurs).
X509v3 Authority Key Identifier	Public key to be used to verify the signature on this certificate or CRL. It enables distinct keys used by the same CA to be distinguished (for example, as key updating occurs).

**Table 6-4** *Field Descriptions for the show crypto certificate filename Command (continued)*

Field	Description
Signature Algorithm	Name of the algorithm used for digital signatures (but not for key exchanges).
Hex Numbers	Actual signature of the certificate. The client can regenerate this signature using the specified algorithm to make sure that the certificate data has not been changed.

## Displaying CRL Information

To display a list of certificate revocation lists (CRLs) to the ACEs or definitions for a specified CRL in a context, use the **show crypto crl** command in Exec mode. The syntax of this command is as follows:

```
show crypto crl { crl_name | all }
```

The keywords and arguments are as follows:

- *crl\_name*—Name of a specific CRL configured in the context. Enter an unquoted alphanumeric string. The ACE displays the definitions for the specified CRL.
- **all**—Displays a lists of all CRLs configured in the context.

For example, to display a list of all CRLs, enter:

```
host1/Admin# show crypto crl all
```

To display the definitions for a specific CRL, for example CRL1, enter:

```
host1/Admin# show crypto crl CRL1
```

Table 6-5 describes the fields in the **show crypto crl** *crl\_name* command output.

**Table 6-5** *Field Descriptions for the show crypto crl Command*

Field	Description
URL	URL where the ACE downloads the CRL.
Last Downloaded	Last time the ACE downloaded the CRL. If the CRL is configured on an SSL-proxy service on a policy map that is not active or the service is not associated with a policy map, the field displays the “not downloaded yet” message.
Total Number of Download Attempts (for This Name of CRL)	Total number of successful download attempts for a named CRL. <b>Note</b> Multiple logical configured CRL names may point to the same CRL data.
Failed Download Attempts (for This Name of CRL)	Number of failed download attempts for a named CRL. <b>Note</b> Multiple logical configured CRL names may point to the same CRL data.
Total Number of Download Attempts for Real CRL Data	Total number of successful download attempts for the real CRL downloaded to the ACE for client authentication on an SSL proxy service.
Failed Download Attempts for Real CRL Data	Number of failed download attempts for the real CRL downloaded to the ACE for client authentication on an SSL proxy service.

**Note**

To view whether the ACE rejects client certificates when the CRL in use is expired, use the **show parameter-map** command.

# Displaying RSA Key Pair Information

To display the key pair file summary and detailed reports, use the **show crypto key** command in Exec mode.

The syntax of this command is as follows:

```
show crypto key {filename | all}
```

The keywords and arguments are as follows:

- *filename*—Name of a specific key pair file. Enter an unquoted alphanumeric string with a maximum of 40 characters. The ACE displays the key pair detailed report for the specified file.
- **all**—Displays the key pair summary report that lists all of the available key pair files.

For example, to display the key pair summary report, enter:

```
host1/Admin# show crypto all
```

Table 6-6 describes the fields in the **show crypto key** command output.

**Table 6-6** Field Descriptions for the **show crypto key** Command

Field	Description
Filename	Name of the key pair file that contains the RSA key pair.
Bit Size	Size of the file.
Type	Type of key exchange algorithm, such as RSA.

The following example shows how to display the detailed report for the public and private keys contained in the MYKEYS.PEM key pair file:

```
host1/Admin# show crypto key MYKEYS.PEM
1024-bit RSA keypair
```

Table 6-7 describes the fields in the **show crypto key filename** command output.

**Table 6-7** Field Descriptions for the **show crypto key filename** Command

Field	Description
Key Size	Size (in bits) of the RSA key pair.
Modulus	Hex value of the public key. The private key modulus is not shown for security purposes.

## Displaying Certificate Chain Group Information

To display the chain group file summary and detailed reports, use the **show crypto chaingroup** command in Exec mode.

The syntax of this command is as follows:

```
show crypto chaingroup {filename | all}
```

The keywords and arguments are as follows:

- *filename*—Name of a specific chain group file. Enter an unquoted alphanumeric string with a maximum of 64 characters. The ACE displays the chain group detailed report for the specified file. The detailed report contains a list of the certificates configured for the chain group.

- **all**—Displays the chain group summary report that lists each of the available chain group files. The summary report also lists the certificates configured for each chain group.

For example, to display the chain group summary report, enter:

```
host1/Admin# show crypto chaingroup all
```

The following example shows how to display the detailed report of the certificates configured for the MYCERTGROUP chain group:

```
host1/Admin# show crypto chaingroup MYCERTGROUP
```

[Table 6-8](#) describes the fields in the **show crypto chaingroup** command output.

**Table 6-8** Field Descriptions for the *show crypto chaingroup* Command

Field	Description
Certificate	Certificate filename.
Subject	Distinguished name of the organization that owns the certificate and possesses the private key.
Issuer	Distinguished name of the CA that issued the certificate.

## Displaying Client Authentication Group Information

To display a list of certificates for each authentication group or the certificates in a specified client authentication group including the Subject and Issuer information for each certificate, use the **show crypto authgroup** command in Exec mode.

The syntax of this command is as follows:

```
show crypto authgroup {group_name | all}
```

The keywords and arguments are as follows:

- *group\_name*—Name of a specific authentication group file. Enter an unquoted alphanumeric string with a maximum of 64 characters.
- **all**—Displays the list of certificates for each authentication groups.

For example, to display the list of certificates for each authentication group, enter:

```
host1/Admin# show crypto authgroup all
```

To display each certificate for the AUTH-CERT1 group including the Subject and Issuer information for each certificate, enter:

```
host1/Admin# show crypto authgroup AUTH-CERT1
```

[Table 6-9](#) describes the fields in the **show crypto authgroup** *group\_name* command output.

**Table 6-9** *Field Descriptions for the show crypto authgroup group\_name Command*

Field	Description
Certificate	Certificate filename.
Subject	Distinguished name of the organization that owns the certificate and possesses the private key.
Issuer	Distinguished name of the CA that issued the certificate.

## Displaying Cached TLS and SSL Session Entries

To display the number of cached TLS and SSL client and server session entries in the current context, use the **show crypto session** command in Exec mode.

The syntax of this command is as follows:

```
show crypto session
```

For example, enter:

```
host1/Admin# show crypto session
```

# Displaying TLS and SSL Statistics

To display TLS and SSL client or server statistics for the current context, use the **show stats crypto** command in Exec mode.

The syntax of this command is as follows:

```
show stats crypto {client | server}
```

The keywords are as follows:

- **client**—Displays the TLS and SSL client statistics.
- **server**—Displays TLS and SSL server statistics.

For example, to display the client statistics, enter:

```
host1/Admin# show stats crypto client
```

To display the server statistics, enter:

```
host1/Admin# show stats crypto server
```

[Table 6-10](#) describes the fields in the **show stats crypto** command output.

**Table 6-10** *Field Descriptions for the show stats crypto Command*

Field	Description
SSL alert... rcvd/sent	Number of times that the standard SSL alert messages received or sent.
SSLv2/v3 client hello received	Number of ClientHello message received.
SSLv3/TLSv1 negotiated protocol	Number of the times that the version used in the connection.
SSLv3 full handshakes	Number of handshakes completed without errors.
SSLv3 resumed handshakes	Number of handshakes resumed by using a session ID.
Cipher sslv3...	Number of times that the cipher suite is used in the connection.

**Table 6-10** *Field Descriptions for the show stats crypto Command (continued)*

Field	Description
TLSv1 full handshakes	Number of handshakes completed without errors.
TLSv1 resumed handshakes	Number of handshakes resumed by using a session ID.
Cipher tlsv1...	Number of times that the cipher suite is used in the connection.
Total SSL client authentications	Number of authenticated client connections. This field increments only when displaying server statistics.
Failed SSL client authentications	Number of client connections that failed authentication. This field increments only when displaying server statistics.
SSL client authentication cache hits	Number of times that an authenticated client reconnects and a cache entry is found. This field increments only when displaying server statistics.
SSL static CRL lookups	Number of lookups against a statically defined CRL.
SSL best effort CRL lookups	Number of lookups using the best effort.
SSL CRL lookup cache hits	Number of CRL lookups where the cache result was used.
SSL revoked certificates	Number of revoked certificates encountered.
SSL CRL download failed	Number of CRL downloads that failed.
Total SSL server authentications	Number of server certificate authentications that the ACE attempted to perform. This field increments only when displaying client statistics.
Failed SSL server authentications	Number of server certificate authentications that failed. This field increments only when displaying client statistics.

**Table 6-10** *Field Descriptions for the show stats crypto Command (continued)*

<b>Field</b>	<b>Description</b>
Handshake FlushRX/TX operations	Number of times that the SSL handshake finished.
Xscale messages rcvd/sent for ME	Number of messages passed between the SSL processors during the SSL handshake.
Xscale rcvd abort msg before hdshk	Number of times that the SSL handshake was aborted.
Finish msg split across ssl recs	Number of times that the SSL Finished message was split by the client into multiple SSL records.
